Abstract: This report concludes a series of articles by the authors devoted to the human factor and published in scientific journals «Industry-4.0s in 2017, 2018. The problem of the human factor is shown from a new point of view in the article, namely: the human factor is not only the limited possibilities of professional activity, due to human physiology, it is, above all, the limited possibilities of technology that does not take into account the characteristics of a person in the human-machine system. There are considered various aspects of this problem.

Keywords: Civil aviation, aviation security, human factor, integrated systems, harmonization of the human factor.

1. Introduction

The human factor (HF) in many industries refers to one of the most common concepts. This concept is especially widely used in civil aviation. It has become a regular occurrence to attribute the blame for most incidents to the human factor, while the understanding of what is related to this factor is often absolutely different. On the one hand, we can definitely consider the human component as present almost everywhere. On the other hand, accusing the human factor of all the events essentially complicates the situation, since we cannot get a real accident picture, although this is not the purpose.

HF is a complex category with a fairly large number of components, not all investigated in case of an incident. HF is an inexhaustible field of research, even interdisciplinary. This is especially important in civil aviation, where, nevertheless, the main studies of the HF are concentrated in the field of flight safety, and even more often in the study of crew teams.

There has not been carried out any scientific research connected with the HF in the field of aviation security, although the importance of the HF is equally important. This work presents some approaches to the study of the HF in aviation security.

2. The human factor and the personnel threat

Aviation security as a scientific area deals with the issues of ensuring the protection of civil aviation from illegal interference in its activities. The objective functional of the system solving these problems is significantly different in its content from other systems as part of the aviation transport system. This fact determines the specifics of the means, methods and procedures used in aviation security. The human factor in the structure of the aviation security system occupies a particularly important place, since up to 80% of negative events are connected with it.

In modern safety systems, including flight safety systems, it is established that the causes of faulty actions of personnel are associated not only with the level of professionally important qualities of the individual, but also with the imperfection of the means of activity and its organization. I.e. the question of reducing the human factor’s negative role is determined by the success in improving the parameters (characteristics) of a person and technology.

It is more complicated in aviation security systems because the procedures of personnel’s professional activities are poorly formalized and algo-rhythmized, characterized by extreme manifestations, have a high degree of ambiguity, and the tasks are poorly structured and poorly formalized.

In terms of aviation security, it is proposed to consider the human (personal) factor as an inevitable evil, excluding a useful component, and all its negative manifestations are classified as security threats. In this case, the methodologies developed to protect the objects of the transport infrastructure can be used to study the human factor in order to reduce and/or eliminate its impact in aviation security, i.e. the well-known formula begins to work: detection-reflection-elimination.

The conceptual construct can be the basis for this approach. Indeed, the factor is the cause driving any process, determining its nature or its individual features, where the cause is considered as the basis for any action. The threat involves the possible, the probable danger, the intention to cause harm. In this case, the concept of factor can be replaced by the concept of threat, and the actions of aircraft personnel in this part can be compared and equated to the actions of the offender, agreeing that these actions are not hostile, antagonistic, but are forced, random, often independent of the intentions of the personnel. In this way the concept of the personnel threat can be introduced.

The personnel threat (PT) in aviation security is a state of inadequate professional readiness of the operator and the situation’s parameters in the safety system, determined by the limit level of the individual’s psychophysiological parameters, allowing the appearance of a negative event. It should be noted that deliberate actions of personnel provoking negative events, even if it is an aviation security officer, automatically translate the situation into an act of unlawful interference (AUI).

3. Some approaches to the study of HF in aviation security

In modern aviation security systems, a person is considered as a source of threats, i.e. the security system should prevent and neutralize the anthropogenic impact. These can be terrorist threats, hooligan actions, negligence, theft, unauthorized photo and video shooting, violations of the regime and labor discipline, and much more. This is one category of threats. We consider personnel threats from the perspective of the man’s imperfections and poor adaptation of the characteristics of the personnel to the protection parameters’ technical means when working with personnel requirements can exceed the level of psychophysiological opportunity of the human-operator.

Aviation management security system is a process of rational behaviour of the system based on the measurement, assessment and analysis of the situation (contingency management) [10]. Contingency management is the process of measuring the parameters of the system, transferring it from one state to another in the interests of the target function, it is contemplated that there is no stage-by-stage approach in the solution of control problems, i.e. there may not be a solution algorithm. In this case, the heuristic approach becomes relevant.

Heuristics can be understood as methods of solving problems in conditions of uncertainty, which are opposed to formal methods of solution. Heuristic methods should be considered as having no prescriptive value, as in the case of using algorithmic methods. A heuristic algorithm is an algorithm for solving a problem, the correctness of which is not proved for all possible cases, but it is known that it gives a fairly good solution in most cases, i.e. it is not completely mathematically justified, but at the same time it is a practically useful algorithm.

Heuristic algorithms and procedures give the greatest effect in combination with the theory of decision-making [11, 12].

The decision-making procedure can be single-criteria and multi-criteria, depending on the complexity of the problem.

If the control efficiency is characterized by some optimal test F:
The simulation prediction is a certain distribution of the intensity of personnel threats on the topology of the transport infrastructure object, which allows identifying extreme points of impact of threats and including them in the list of priority when monitoring the situation in the TF (transport facility).

The situation in the TF related to the security is assessed through the dynamics of incidents, which represent threat manifestation. It is through the incident that the negative impact of personnel is manifested to the maximum extent, so the task is to make a decision on the management of these personnel, i.e. to exclude this negative impact. The control system should provide the possibility of automated adjustment of the work’s algorithm with the inclusion of tools for reconstruction of the structure of the aviation security management system.

4. Conclusion

The problems in the field of aviation security related to the human factor are multifaceted and quite complex. Classical approaches to solving these problems have almost reached their limits. There are needed new approaches, one of which you can find in this report.

The idea of the new approach is a fundamental revision of the human factor’s physical meaning, realizing that the HF in rigorous definition is not a factor, but a much more complex and multifaceted category relating to complex systems and having an objective functional that is not amenable to the strict mathematical investigation.

The authors introduce a new concept: the personnel threat, by which we understand the state of inadequacy of the operator’s professional readiness and the parameters of the situation in the security system, determined by the limit level of the individual’s psychophysiological parameters, allowing a negative event appearance. Monitoring of this threat and its study involves the use of known methods, mathematical or heuristic, with their specific adaptation and limitations, subsequent measurement and analysis in a quantitative format, which simplifies the procedure for making decisions on personnel management.

The suggested approach increases the level of aviation security of the transport infrastructure’s object by reducing the level of negative impact from the aviation personnel.

INFLUENCE OF LIBERALIZATION ON LONG-DISTANCE RAIL TRANSPORT IN THE CZECH REPUBLIC

Ing. Vít Janoš, PhD., Ing. Milan Kříž
Faculty of Transportation Sciences – Czech Technical University in Prague, Czech Republic
janos@fd.cvut.cz

Abstract: In the Czech Republic, the rail transport market has been liberalized for several years - in addition to public services, commercial services of individual rail carriers operate too. Public services in long-distance rail transport are ordered by the Czech Ministry of Transport. In December 2019, the 10-year contract between Czech Ministry of Transport and Czech Railways will end. The approaching end of this contract was connected with great interest of other rail carriers, which led to the fact, that the Czech Ministry of Transport demanded individual long-distance rail lines in the form of so called “market consultations”. Preparing of the operational performance of individual long-distance rail lines for the needs of market consultations was a great challenge on the field of transport-planning. As a result, from December 2019 there will operate 4 different rail carriers in ordered long-distance rail transport in The Czech Republic and this situation is unique in its form and unparalleled throughout the EU.

Keywords: RAILWAY TRANSPORT, PUBLIC TRAFFIC, RAILWAY TECHNOLOGY, TIMETABLE DESIGNING, PERIODIC TIMETABLE, OPEN-ACCESS, CAPACITY, LIBERALIZATION

1. Order of public rail services in the Czech Republic

Since 2005, rail transport in the Czech Republic regionalised. 14 regions is responsible for ordering regional rail transport, the Ministry of Transport is responsible for long-distance rail transport order.

Public transport services in the Czech Republic are characterized by the fact that they represent in general a performance for which the sum of revenues is not sufficient to cover costs associated with the services.

Order of the Ministry of Transport is focused on the fixed interval connection between each regional capitals and other major residential areas in the Czech Republic.

Overall, in 2018 in the Czech Republic, the total volume of train-kilometers in ordered long-distance transport was about 35 million train km.

A feature of public rail services in the order of Ministry of Transport and the Regions is also the fact, that it is an “open” system, which works across the network unified fare system, so there is time, space and tariff interconnection of services. A feature of the system is not “denial of passengers” (i.e., inability due to lack of transport capacity of lines), while no reservations required (no link between a ticket and particular train). It is natural, that such a generally high quality parameters of public services cannot be met without compensation from national budget.

The total amount of payments from national budget for compensation for ordering of long-distance rail passenger transport was in 2018 CZK 4.1 billion (approximately EUR 158 million)

The main direct awarded 10-year public contract between Czech Ministry of Transport and Czech railways ends in December 2019.

2. The liberalization of the rail market in the Czech Republic

The current practice in the Czech Republic is still mostly represented in rail passenger transport services by direct selecting of the train operating company (TOC). In 2009, when Czech Ministry of Transport signed the 10-year contract with Czech Railways to provide transport services in long-distance traffic, followed extensive criticism from another TOC’s. Czech private TOC’s have criticized the closeness of the public service market and demanded public procurement for rail through transparent selection.

Before 2009, contract award after competition of TOC’s was made on long-distance lines Pardubice - Liberec and Plzeň - Most. Both of these competitions were won in 2005 by Czech railways. Despite the victory of the national carrier, these competitions led to a reduction of compensation.

However, in 2009, there were timewise unable to prepare further competitions into the process. Despite the fact, that the majority of transport volume in long distance rail transport has been selected directly, reported by the Czech Republic to support the liberalization of rail transport.

This declaration liberalization of passenger rail market has two specific implications:

1) official timetable for market opening in long-distance transport, the opportunity to compete in selected contracts
2) liberal access to railway infrastructure - Open Access

After closing of the 10-year contract between Czech Ministry of Transport and Czech Railways, the private TOC’s in the Czech Republic focused on developing open-access services.

2.1. Open-Access in the Czech Republic

In the Czech Republic, additionally to the public services, there is a fully liberal approach to infrastructure – Open Access, without any restriction. Each TOC can apply to the transport infrastructure access authority (ÚPDI) and then may ask the infrastructure manager (IM) for capacity and IM (Railway Infrastructure Administration – RIA - ŽSÚDČ) will be required to allocate infrastructure capacity.

The first project in the Czech railway network, which had features of Open Access approach were the SC Pendolino trains between Prague and Ostrava. These SC-trains operate Czech Railways on their commercial risks, with mandatory reservation and limited passenger capacity and costs for transportation of these trains is significantly above the level of fares on trains, which are ordered and form a public service.

The second Open Access project are the Regiojet trains of (former) Student Agency company running on the route Praha – Ostrava – Havířov (- Žilina). Again, these are trains to TOC commercial risk, with mandatory reservation (seat reservation is included in the ticket), with limited passenger capacity, but the price for the carriage of these trains is comparable to fares on trains, which are ordered and form a public service.

The third Open Access project is a LEO Express, i.e. Leo Express trains again on the route Praha - Ostrava. As in the case of
RegioJet, in this case, the connections to the commercial risk of the TOC will have to provide mandatory seat reservation will have a limited capacity for passengers.

All Open-Access projects began to develop. Czech Railways, for example, has taken over the international night trains to their commercial risk. RegioJet expanded its activities to include connections Prague - Wien and Prague - Bratislava, Leo Express expanded its range of services to include connections Prague - Krakow and Prague - Staré Město u Uherského Hradiště.

This battle of TOCs in Open-access services is unprecedented in the European railway area. Already less than one year of sharp competition between three different TOC’s has been indicated, that commercial Open-Access services are very unstable in time. Changing time position of the trains, changing and different stops, variable and unstable number of connections etc., such services cannot be reasonably operationally integrated into the open transport system and they can hardly serve as a fixed part of the territory's transport service.

2.2. Market opening in long distance transport

Market opening in long-distance rail transport should solve as a possibility to increase quality / price ratio in the Czech rail transport. Ministry of Transport expects, that the current level of compensation will be held and serve to reach higher quality or higher range of passenger rail services performance. A prerequisite is the case, it can maintain a stable long-term financing of the railway sector and there will be no significant changes in the amount of available financial performance.

After one-off competitions in the year 2005 (lines Pradubice - Liberec and Plzeň - Most) has the Czech Ministry of Transport already in 2011 published a schedule for market opening in long-distance rail transport. In March 2012 have been published specifications for the first competition (line Olomouc - Kromov - Ostrava).

Although the tender for the line Olomouc - Kromov - Ostrava was canceled for formal reasons in 2013, the competition trend continued. In 2014, the preparation of the tender for the line Plzeň - Most (where the contract from 2006 was to end in 2015) was launched. Due to procedural delays, the contract from 2006 was extended by 2 years - but the tender was in the end finally canceled on the basis of objections from Czech Railways. However, there occurred a breakthrough situation, when the Ministry of Transport used the possibility of direct awarding institute and assigned directly to the winner of the canceled competition (TOC GWTR) the operation on the line Plzeň - Most (with level of compensation offered in the cancelled tender). It was a clear signal sent to the market of rail operators, that the liberalization of the rail market would not be stopped due to procedural obstruction.

For a main contract with Czech Railways from 2009, which ends in December 2019, the Ministry of Transport prepared a follow-up of direct assignment of the contract. The rules for access to public services are laid down in the amendment to Regulation (EC) No 1370/2007, which is part of the fourth railway package. Applicability of direct award of the contract in the passenger rail services is in force to 25. December 2023.

However, as the private TOC’s in the Czech Republic have announced their relevant interest for participating in long-distance rail-services, the Ministry of Transport has notified the order of long-distance after 2019 transport in the Official journal of the EU on a per-line basis, with a different duration, so that this corresponds to the published schedule for competitions in rail public services planned in years 2020 - 2034.

3. Procedure for concluding new contracts after 2019

The Ministry of Transport access is clear that the priority-driven process in which is preserved the networked public rail transport (in Czech and Central European scale) and will clearly set in advance in market access conditions, including rules on mutual recognition of travel documents and the use of station buildings.

The principle is, that the Czech Ministry of Transport published in spring of 2017 in the Official journal of the EU, that all long-distance lines from 12/2019 will be reassigned. Each line had its own notification - all as a direct allocation for CD.

Until spring 2018 have The Ministry of Transport negotiated with Czech Railways, what transport parameters (vehicles, performance quality, timetable) of which lines is possible to offer for next contract period.

Approximately in March / April 2018 got The Ministry of Transport offer from Czech Railways on all lines and additionally also offers on some lines from another TOC’s.

Than was necessary to sort, on which lines are the offers of another operators worse favorable, than the offer from Czech railways. Because the third operators have not previously negotiated with The Ministry of Transport, were the offers not comparable. The Ministry of Transport has then made operational “packages” and asked with these packages new request to all interested TOC’s (including Czech Railways) - for to update offer specification.

Content of each operational “package” was line (or more lines) with such timetable and quality requirements, which was negotiated with Czech Railways between 2017 - 2018. So the assignment of each package was always direct assignment - only based “market consultation”. The requests to TOC’s for offers for operating these "package" - so called "shoot-out" - ran between June - November 2018.

3.1. Technological structure of operational "packages"

In order to formulate the content of each operational package, it was necessary to set their structure, in particular the operational closeness and consistency.

A task was the basic determination of number of trains and their position in nodes (marketing timetable), defining the size of train-sets including regular and seasonal capacity strengths and timetabling (calculation of travel times).

Existing interconnected traffic provides a variety of synergies (typically vehicle-to-line transitions) and it was not desirable to lose these benefits.

For the operational separation of the lines and the arrangement of the operating structure of the packages, it was necessary to reflect the number of vehicles in relation to the timetable. On the operational side, such lines were grouped into individual packages, taking into account the operational background, necessary transport capacities and traction.

From the timetable point of view, it was often necessary to add new connection or links, for to isolate individual packages and close them to the functional cycles. In this step, it was necessary to reflect IPT nodes, bindings and schedule boundary conditions, transfer / changing nodes and intended length intervals for peak-and-off-peak hours.

The author’s team used their previously published approach, which combines timetable proposal and operational concept with cycles of vehicles, in mutual repeating iteration steps.

Approach to the timetable creating is as follows:

1) defining IPT nodes and intervals, calculate the number of vehicles for “basic periodical operation"
2) defining a specific operation in the peak hours and minimizing the number of vehicles in peak period; ideally for the number required in previous point 1

3) operational optimization and ensuring operational efficiency (refueling, maintenance, cleaning...)

4) adaptation of timetables in the evening hours (to minimize the number of vehicles, reduction of total working times)

The aim is to ensure maximum operational efficiency within a defined operational file.

4. Conclusion

Based on so operationally and transportly defined content of packages were made so called "shoots" - every interested TOC gave its offer to the Ministry of Transport.

As first package, there was already in June 2018 direct assigned a package including a line Pardubice - Liberec. The winner of this "shoot-out" was Czech railways.

As second package, there was direct assigned a package including lines Praha - Olomouc - Žilina and Praha - Olomouc - Luhačovice. The winner of this "shoot-out" was Czech railways too.

As third package, there was direct assigned a package including line Brno - Bohumin. The winner of this "shoot-out" was Czech private railway operator Regiojet.

As fourth package, there were direct assigned a package including large network of fast trains in diesel-traction in middle Bohemia (Praha - Tanvald, Praha - Rakovník, Praha - Písek - České Budějovice, Kolin - Nový Bor). The winner of this "shoot-out" was international operator Arriva.

Market opening in long-distance rail transport should solve as a possibility to increase quality / price ratio in the Czech rail. The whole money, which was saved by "shoot-outs" of these packages, will be from December 2019 inserted in broad timetable extension - and not only on the lines included in these packages, but nearly on all lines in the fast-train network.

This way of liberalization of public rail services using direct assignment has currently in Europe no analogy. Although there has been a clear commitment to a functional operational arrangement, it will be exciting to see, how this system will work in practice, with the launch of a new timetable in December 2019, and above all, how passengers will react to this new system. A major challenge will be the coordination of individual transport services in operation to maintain the functionality and integrity of the rail transport system.

Abstract: Determination the annual quantities of pollutant emissions in road transport emitted into the atmosphere, with the timely delivery of reliable information to all interested parties, conditions are created for raising the level of public awareness of environmental protection. Determining the amount of pollutants emitted facilitates monitoring of trends in order to lower the level of risk from their negative effect. This paper presents the results of calculating the amount of emitted pollutant emissions from road motor vehicles and determining emissions of pollutants on state roads I and II in the Republic of Serbia for the period 2013 to 2015 using the current version of COPERT 5 software. On the basis of the calculated emission of pollutants by shares and the belonging of the sections to the corresponding squares, the spatial distribution according to the squares of the European Monitoring and Evaluation Program (EMEP) network is shown.

Keywords: ATMOSPHERIC POLLUTANT, COPERT 5, ROAD SECTION, EMEP NETWORK

1. Introduction

Determining emissions of pollutants in road transport is very complex and requires the modeling of input parameters. In addition to the pollution forecast, models and their results are used to make decisions when creating strategies in order to reduce the negative impact on the environment. With the help of the model, the effects of the applied measures are evaluated. In order to apply the concept of sustainable development to the road transport sector, it is necessary to know the participation of road transport in air pollution, which is provided by models for estimating emissions from road transport. By determining the annual quantities of pollutants from road transport in the atmosphere, with the timely delivery of reliable information to all interested parties, conditions for raising the level of public awareness of environmental protection are created. Determining the amount of pollutants emitted also facilitates the monitoring of trends in order to lower the level of risk from their negative effect. All variables that affect the amount of pollutant emissions in road transport is necessary to accurately determine or evaluate in order to enable analysis of the effects of stimulating and restrictive measures (cost-benefit analysis, intangible effects, etc.) in order to achieve sustainability of road transport. The assessment method presented in this paper provides a good basis for assessing the feasibility of fiscal measures to reduce emissions from road transport, or to increase its sustainability, as well as to estimate pollutant emission generated by vehicles on state roads I and II category. The subject of this paper is to calculate the emissions of pollutants from road vehicles and to determine emissions of pollutants on state roads I and II category using the current version of COPERT 5 software for the period from 2013 to 2015. The subject of research is also determining the influence of the dominant exploitation conditions on the emission of pollutants. On the basis of the estimated distance traveled, the prevailing conditions of exploitation and the level of pollutant emission standards of vehicles, it is determined the technical condition of vehicles and the final value of vehicle emissions on roads. For all sections of state roads I and II category based on data from automatic counters or weighted data on average annual daily traffic (AADT), structure of vehicle fleet, section length and average speed on a section (measured or expertly assessed), the emissions of a set of pollutants for individual sections by category of vehicle are calculated. Based on the calculated emissions of pollutants per road section and the affiliation of the section with the corresponding squares, the spatial distribution is made according to the squares of the European Monitoring and Evaluation Programme (EMEP) network.

2. Model for assessment of pollutants emissions

In order to quantify the emission of gaseous pollutants derived from road transport in this paper, the results obtained using the COPERT 5 software tool (April, 2017) are presented. COPERT (COmpute Program to calculate Emissions from Road Transport) is one of the European tools for calculating emissions according to the Convention on Long-Range Transboundary Air Pollution (CLRTAP), in accordance with the requirements set by the Cooperation Program for monitoring and evaluation of the EMEP and the European Environment Agency (EEA), which financed the development of COPERT within the activities of the European Topic Center for Environmental Protection air and climate change [1, 2].

In order to carry out the assessment of emissions from road transport by using the COPERT 5 software tool, it is necessary to collect extensive input data. Prior to any evaluation or use of the software, it was necessary to collect data on:
- weather (climatic) conditions during the year,
- specific characteristics of all types of fuel in sales,
- total (annual) consumption of all types of fuel,
- a vehicle fleet classified according to the required categories, subcategories and vehicle emission technologies (number of vehicles)
- the average distance traveled for each category of vehicle (based on a special survey),
- average speeds of vehicles by categories of vehicles and roads,
- participation of the mileage by categories of vehicles and roads (urban, rural and highway) in percentages.

Input data for the Republic of Serbia, which were available in official records or statistics of state institutions and bodies, were collected from the Statistical Office of the Republic of Serbia (data on sold / spent fuel in traffic and transport, data on border traffic of passenger and freight vehicles, etc.) and the Republic Hydrometeorological Institute of Serbia (data on dominant weather - hydrometeorological conditions). After analyzing the data, the method of their correction, i.e. bringing in the form required by the COPERT 5 model, has been determined.

Determination of the structure of the vehicle fleet on the first and second road categories was done by adopting the relevant national vehicle fleet structure, and according to the average annual daily traffic (AADT) by category of vehicle.
The only relevant source of data on hydrometeorological (weather) conditions in the Republic of Serbia is the Meteorological Yearbook issued by the Republic Hydrometeorological Service of Serbia (RHSS). RHSS disposes of so-called “Climatological” data from 1949 to 2015 with the exception of the period from 1980 to 1989. These reports contain data on average monthly minimum and maximum temperatures, average monthly air pressure and relative humidity.

Climatological data required for the calculation are:
- mean maximum monthly temperature (°C),
- mean minimum monthly temperature (°C),
- air pressure (kPa) and
- relative humidity (%).

These input data are necessary to obtain the average monthly conditions in which vehicles are used. They are used to assess the impact of a cold start on vehicle emissions, as well as air conditioners, both for the purpose of cooling during the summer (warmer months), as well as heating during winter, as well as reducing air humidity (over the whole year).

Consumption or amount of spent fuel is one of the indicators of transport activities. It is used as a control indicator for determining and possibly correcting the average annual traveled route of certain vehicle categories. Average fuel consumption is a measure of the efficiency of fuel utilization as the ratio between the distance traveled and the amount of fuel consumed. Given that spent fuel is an important factor in air pollution, a large number of countries have introduced strict fuel consumption related restrictions.

The COPERT 5 software tool calculates energy consumption rather than the fuel consumption to facilitate the calculation of energy consumption for new types of vehicles (hybrid vehicles - plug-in vehicles with gasoline and hybrid vehicles powered by diesel; electric vehicles drive - batteries and electricity, fuel cells (N2) and electric drive).

Access to the COPERT 5 model implies that the following information are entered for the vehicle: vehicle type, vehicle speed (km/h), primary fuel consumption (TJ), primary fuel content (MJ/kg), fuel mixture used, in a mixture of fuel (%). The COPERT 5 model compares the statistical and calculated energy consumption, modifies the input data (for example, the traveled vehicle distance) and repeats the procedure for calculating the amount of emitted pollutants.

The source of data for determining size of the national vehicle fleet is data on all national vehicles (excluding fleet of military and police) located in the base, i.e., records of registered vehicles. In order to be able to use the data from registered vehicle records for the calculation according to the COPERT 5 model, it is necessary to adapt the existing vehicle classification to the categorization of the vehicle defined in this model.

Sources that have been processed for the purpose of collecting data on vehicle activities in the survey are as follows:

a) passenger car user survey conducted in 2017;
b) regular survey conducted in 2013 and 2016 in transport companies for the transport of passengers (urban and intercity buses) and for the transport of goods (delivery and cargo vehicles);
c) average annual daily traffic on the roads of the first and second category of the Republic of Serbia in the period 2013-2015.

All of the aforementioned and available data were used in terms of obtaining the most reliable estimation, in the first place, the number of vehicles on the road network of the Republic of Serbia, and then the realized route of those vehicles. Values of certain input data, for which there is no record, or not obtained through research, were adopted according to the project recommendations [1]. According to this project the value of the average length of travel should be in the range of 8 to 15 km, but in the absence of data, the value is 12.4 km, which represents the average length of travel in the EU Member States.

3. Emission of the national vehicle fleet

The total emissions of pollutants of the national vehicle fleet are shown in Fig. 1 and Fig. 2. Passenger vehicles mostly affect CO, CO₂, SO₂ and Pb emissions, while commercial vehicles have the largest share in NOₓ, PM₂.₅ and PM₁₀ emissions (Fig. 3 - Fig. 5).
This paper presents the results of the Study on estimation of emissions of pollutants in the atmosphere from transport on state roads I and II category for the period from 2013 to 2015 [3].

The data on the vehicle fleet of the Republic of Serbia and the emission factors from the COPERT 5 software tool have been used for the calculation of the emissions of exhaust gases. For all state roads (over 100 roads) and sections (over 1,000), for each year of the observed period, 2013, 2014 and 2015, the amount of pollutants emitted is calculated.

The following data were used for the calculation:

- average annual daily traffic per vehicle category by road section,
- length of road section,
- average speed of vehicles on road section and
- emission of pollutants by vehicle category (g/km).

Based on the available data on the lengths of the road sections and the average annual daily traffic, the total millage traveled by road categories (in autocilometers) and road sections was determined. The average speed of the vehicle on the sections are calculated based on the available time travel speeds of the vehicles read on the traffic counters. The unit emission of pollutants is expressed in grams per autocilometer by category of vehicle (passenger car, bus, light duty vehicle, medium freight vehicle, heavy duty vehicle, articulated vehicle). In order to determine the unit's emissions, the software tool COPERT 5 and the structure of the fleet of the Republic of Serbia were used in 2013, 2014 and 2015.
The total emission of pollutants on the road section during the year is the product of the unit emission in the calculated autokilometer and the total number of autokilometers per vehicle category.

Total emissions of pollutants on state roads I and II category, by category of vehicles, in the period from 2013 to 2015 is shown in Table 1.

Table 1: Total emission of pollutants on state roads I and II category in the period 2013-2015

5. Spatial distribution by squares of the EMEP network

On the basis of the calculated emission of pollutants by road sections and the belonging of the sections to the corresponding squares, the spatial distribution according to the squares of the Program of European Monitoring and Evaluation (EMEP) is made.

The emission level of the three selected pollutants according to the EMEP network squares in 2015 are shown in the following figures (Fig. 6 - Fig. 8). The highest emission of pollutants is in the squares where the length of the road network is large and the high value of the PGDS (squares 12.2, 12.1, 12.7, 12.8, etc.)

Fig. 6 Emission of CO per network squares, year 2015

Fig. 7 Emission of NO, per network square, 2015 year
6. Conclusion

In order to calculate the amount of pollutants emitted in this study, the model and software tool of the European Environment Agency - COPERT 5 was used.

For the purpose of the calculation of emissions, systematized data on the fleet, mileage of the vehicle, climatological data and other elements necessary for the calculation were collected. For the observed period, the structure of the vehicle fleet was presented and the average annual mileage by category of vehicles was presented. Finally, as a result of using the COPERT 5 model, the quantities of emitted pollutants from road transport at the national level for the period from 2013 to 2015, as well as the quantities of emitted pollutants on the first and second roads in 2013, 2014 and 2015, as shown in the EMEP squares.

Depending on the quality and precision of the input data, depends the level of quality of the results of the calculation. The results of the calculation can serve as a basis for modeling different scenarios of changing the structure of the vehicle fleet, transport policy, ways of using roads and vehicles and the effects of these changes on the environment and the impact of these changes on the policy of taxation of the possession and use of roads and vehicles, both at national and at the local level.

The basic effect of applying the results of this study should be the creation of conditions for reducing the amount of pollutants emitted for the realization of a certain amount of transport work in order to reduce the adverse impact of vehicles on the environment.

Abstract: Transportation from receiving terminals and condensed fuel gas production plants is accomplished by sea, railway and road transport using the standard (ISO) tank-containing, dedicated tanks and cryogenic semi-trailers.

Recently, the 20 ft and 40 ft tank containers, optimally adapted for multimodal transport have become commonplace. The use of cryogenic semi-trailers with vacuum-perlite, polyurethane, multi-layer and combined insulation with a capacity of up to 54,000 liters of condensed fuel gas allows for creating a flexible and elastic delivery system to the market.

KEY WORDS: LAND TRANSPORT, SEA TRANSPORT, GAS CARRIER, EXPLOSION SAFETY.

1. Introduction

Liquefied Natural Gas (LNG) represents the main alternative to pipeline supplies of gas. In liquefied form, natural gas (methane) can be stored and transported across long distances, contributing to diversification of supply and enhancing energy security in Europe. The gas market in the EU is characterised by gradually declining domestic consumption and more rapidly declining domestic production. Import needs are likely to increase in the short and medium term, and remain broadly stable in the longer term.

The International Energy Agency and the European Commission expect this trend to continue in the coming years. Major new LNG suppliers are emerging and the prospect of US shale gas being exported as LNG could further reshape global gas markets. The European Commission is developing an EU strategy for LNG and gas storage, one of several measures under the Energy Union package to improve energy security and diversify sources of supply. Infrastructure projects, often with EU funding, are helping several Member States to access LNG supplies, while others have sufficient import capacity to meet expected future needs. A strategic emphasis on LNG is consistent with the recommendations of the European Council and the European Parliament.

Transportation from receiving terminals and condensed fuel gas production plants is accomplished by sea, railway and road transport using the standard (ISO) tank-containing, dedicated tanks and cryogenic semi-trailers.

The first automobile transportations of liquefied natural gas in the United States dates back to the mid-1960s. In this time period there were not created the special designs of road tankers intended for transportation of liquid gases. Transportations were mostly of an experimental nature and were carried out in modernized vessels engineered for transportation of liquid hydrogen and nitrogen.

A huge increase in the number of consumers and the volume of deliveries of liquefied gas raised the question of creating specially engineered road tankers for transportation of large quantities of liquid gas. When developing the design of tanks, it was necessary to take into account a number of conditions, for example, to fit within the established dimensions for a trailer coupled with a towing vehicle. In this regard, the maximum length of a truck with a trailer was required to be less than 12.2 m, and the width - 2.44 m. The type of transportation was also taken into account. In this case, the trace route was taken into account, as well as whether the supplies are transit or they are intended for a single consumer. In addition to that, the design of a vehicle for transportation of liquefied gas must be approved by the Ministry of Transport. The first road-tankers for transportation of liquefied gas were limited both by the dimensions and weight [1].

Since the limitations on the dimensions and of road-tankers for transportation of liquid gases were established, the tanks with the increased working pressure (more than 2.8 kg/cm²) had been considered to be the preferred option. The use of these tanks has enabled to produce pouring the liquid gas without the use of the special-purpose discharge pumps. However, automobile transportations of liquefied gas remained low-efficient, since the highly flammable and explosive cryogens required installing expensive equipment, as well as the availability of fire-fighting equipment.

One of the main factors that need to be resolved is the determination of the optimal working pressure in the tank. In the light of the accumulated operating experience, the pressure of about 4.9 kg/cm² proved to be most appropriate.

Liquefied gas is used for both covering the peaks in uneven gas consumption, and as the buffer fuel and raw materials in the event of temporary shutdown of gas pipeline. In road transport of liquefied gas, great attention is paid to ensuring their explosion safety and control systems during discharge, loading and gas shipment. Two pressure gauges are installed on the tank, by which the driver controls the pressure in the tank during transport. A liquid level sensor, of the type of a differential pressure gauge, is calibrated in inches of water gauge. On the pipelines block, there is a table of conversion of readings of a differential pressure gauge into gallons. A remote-control system for the filling and emptying of tanks is provided.

When discharging liquid gas, part of it is skipped through the regasifier, after which it is returned into the tank. The operator maintains a constant control over the pressure in the tank, brings it to a specified value, and then turns on the taps and discharges the liquid gas.

A number of companies widely introduce computer engineering in supply maintenance practice. In particular, a program has been developed for calculating the operating schedule for preventive maintenance of vehicles for transportation of liquefied gas.

When designing the road-tankers, it is advisable to take into account the experience acquired with designing tanks for transport of other liquid gases - hydrogen, nitrogen, oxygen, and argon. The reliable thermal insulation of vehicles for fuel gas from the environment is due to the fact that the ambient temperature is 200 °C higher than the temperature of the liquid to be carried. The thermal insulation reduces evaporative losses. Besides, according to standards for occupational safety, the uncontrolled evaporation of gas during transport is unacceptable. Good insulation is the key to the economically optimal conditions for transportation of cryogenic liquids.

Insulation of the first transport tanks was carried out by filling the insulating space with powder, such as diatomite or magnesium carbonate. There is a way to insulate the container with powder under vacuum. The effectiveness of insulation by virtue of the provision of vacuum in the insulation cavity between the outer shell and the inner wall of the tank has increased 10 times. The thermal conductivity of this insulation is about 10⁻³ kcal/m·hr·°C. In addition, the vacuum insulation has the following advantages: the thickness of thermal insulation is reduced; at the set maximum diameter of the tank, the capacity of the latter increases due to the increase in the diameter of its internal tank, the wall thickness of the internal tank might be small due to a slight rise in pressure during transportation in the tank vapor space above the liquid to be carried.
2. Preconditions and means for resolving the problem

The outer shell of the tank is designed on the atmospheric pressure. The dimensions of this shell, which is a cylindrical tank with a big moment of resistance, allow for using it as a chassis of self-supporting semi-trailer.

Experience shows that the price of the tank with the vacuum powder insulation is only slightly higher, and sometimes is even lower than the price of the tank insulated only with powder. For the life time support of the vacuum powder insulation, it is necessary to exercise the pilot-testing in the manufacture of the tank shell. The pilot-testing includes the ultrasonic test of the cylinder and the bottoms, the X-ray examination of the weld seams and leakage detection using helium by means of a mass-spectrometer of both the inner and outer walls of the tank, as well as the pipelines mounted between both tanks.

Switching of partial flow of cargo into the tank-containers is considered to be a promising option for improving the rail transport economy. This is a relatively new vehicle for transportation of liquefied fuel gas. The tank-containers represent a modern and effective way to transport liquefied fuel gases.

Advantages of transportation of fuel gases in tank-containers are as follows:
- improvement of the rail transport economy;
- solving the problem of rolling stock deficit;
- shortening the time of transportation (time require for decanting of cargo, car detention due to the limited power capacity of the decanting stations);
- reducing dependence on the monopolized systems of storage and transfer;- exclusion of losses of product in evaporation and maintaining its chemical properties, owing to the exclusion of repeated decanting of cargo (in places of transfer, along the joint of a change of transport mode or the width of the railroad gauge);
- the geographical expansion of sales (door-to-door delivery to consumers, even in the absence of traditional infrastructure for transportation of fuel gases);
- additional opportunities to increase the number of fuel gas retail outlets, since the tank-containers can be used as repository and reservoirs.

Considering world practice and tendencies of market development, experts regard as inevitable the development of tank-container transportations. This view is supported by the fact that in the world transportation containerization is a driving force behind the development of logistics services. It should also be borne in mind that a growth factor in demand for this means of transportation through the South Caucasus transport corridor may be the implementation of the gas program of Azerbaijan, Kazakhstan and Turkmenistan.

Tank-containers meet precisely all the requirements imposed on them from the part of suppliers and consumers of liquefied fuel gas. First of all, the tank-containers are designed to operate at low temperatures. The temperature range, at which products retain their properties makes up from - 500C to + 500C. Another advantage of the modern container is the use of shut-off equipment, which reduces the cost of products, and makes them maintainable.

Maritime shipping

Tank-container is a tank for transportation of liquid bulk and gaseous cargo. Modules of this type are optimal for multimodal transportation, because when changing the type of transport, they do not require technically challenging repacking of contents. They are in demand in the field of transportation and sale of fuel and energy resources.

Structurally, the tank-container is a cylindrical metal cargo block in a rectangular frame. Its capacity is 25-35 m³. The discharge mechanism of the tank-container can be made either as a simple gravitational discharge or as a system for pumping the contents under the pressure using the pumps. Their bodies are made of chemically resistant stainless steel. The hardness of the frames meets the ISO requirements. The combination of these parameters ensures safe transhipment and stacking of loaded equipment.

The tank container has unique advantages over the advanced standard block:
- It guarantees 100% safety of transportation of highly combustible and explosive cargo, including different types of fuel;
- The original discharge system allows for unloading the containers quickly and minimizing losses of the contents;
- The tank-container fits 60% more liquid or gaseous substances, compared to the similar standard block, and therefore provides savings in logistics more than twice and increases the profitability of business-projects.

The 20-foot tank-containers fall under the category of fast-payback equipment with high profitability. Transport of tank-containers is carried out on the railway platforms, on decks and under decks of ships, by motor transport.

- Maritime transport of containers is carried out on decks of ships of an ordinary type and on decks and in the container cells of specialized the container carriers.
- During transport of tank-containers by public roads, there are used the container-carriers and semi-trailers equipped with the container mounting devices.

Tank containers are divided into several types, which in turn mean suitability for transportation of goods of a certain kind, in accordance with the specification in various categories, ranging from IMO0 (food products) to IMO7 (cryogenic gases).

The IMO7 category covers tanks for transportation of liquefied or pressurized gas, which typically has the operating pressure more than 7 bar. The variety of gas transported in such tanks is numerous, and there is no “standard” specification for such tanks for the operating pressure. The type of tank will depend on the technical characteristics of transported product. In all cases, the exact nature of product to be transported must be known in advance in order to determine the required operating pressures. These tanks are used for products such as butane, propane, liquefied petroleum gas.

Tank-containers, being a multimodal vehicle for international transportations, comply with international and national requirements for vehicles carrying dangerous goods, and tank-containers, should not be offered for carriage, if [2]:
- In an ullage, the movement of liquid within the tank may produce an unacceptable hydraulic force;
- Tank is unpressurized;
- Failures are such that the integrity of tank-container and its lifting and mounting devices can be compromised;
- Service equipment has not been examined and it has not been established whether it is in proper operating conditions.

In the process of transportation, tank containers should be adequately protected from lateral and longitudinal impacts and from overturning. If the hull and service equipment have such design, which is able to withstand impacts or overturning, but such protection is not required.

The examples for the protection of hull at collision:
- side impact protection may consist, for example, of longitudinal beams protecting the hull on both sides at the centerline level;
- the protection of hull from overturning may consist, for example, of reinforcing rings or beams, fixed across the frame;
- back impact protection may consist of a collision bumper or frame;
- the external nozzles must be so designed or protected so that they can prevent the release of contents on impact or if tank was overturned onto the nozzles.
Untreated and non-degassed empty tank-containers must meet the same requirements as tank-containers filled with relevant transported substances.

Displacement of container-tanks during an overload should be made smoothly, without jolts. The collision of tank-containers with vehicles, containers or other items shall be prohibited.

The carriage of tank-containers by motor transport is increasingly demanded in the intermodal traffic, when different types of transport interact with each other, when changing the rail gauges, or when delivering to hard-to-reach areas, where there is no railway line and where this container can be delivered by car.

Transportation in tank-containers is economically beneficial for exporters and importers, since cargo is not overflowed either when changing gauge or in ports when transshipping onto a vessel, which rules out losses of cargo that inevitably occur from spillover, and besides, transportation of containers by rail is considerably cheaper than transportation by car.

The dimensions and coupling sizes of ISO-standard tank-container fully coincide with the sizes of a dry cargo container. Due to the aging of the rail car-tank fleet for transportation of dangerous goods and the minimum production of new rolling stock, the percentage of dangerous goods transported in tank-containers will increase in the future.

Given the lack of the necessity of intermediate cargo transshipment in multimodal transportation, tank containers are the most economical and practical. Advantages of tank-containers:

1. Tank-container – the means for safe transportation of liquefied gases. Safety of international transport is provided by a well-developed world system of certification of tank-containers, inspection, repairing, testing, and insurance of containers and cargo;
2. The absence of additional overflow operations in the case of combined carriage by several types of transport from the manufacturer of cargo to the consumer, which makes it possible to exclude operations transshipment of product when changing the type of transport or crossing borders, in order to maintain the product’s factory quality;
3. The possibility of international transportation under the customs seals, applied during cargo shipping anywhere on Earth crossing any number of state borders;
4. The possibility of warehousing and temporary storage of goods in tank-containers without immediate unloading;
5. The solid structure of tank-containers that allows for stacking in several tiers;
6. No need for special tracks leading to the places of discharge and filling of product;
7. The possibility of direct inclusion in the technological cycles of chemical, oil- and gas-processing enterprises and so on.

Maritime transport of containers is carried out on decks of ships of an ordinary type and on decks and in the container cells of specialized the container carriers. The rules for the carriage of tank-containers by sea, as well as the requirements for tank-containers are regulated by the International Maritime Dangerous Goods Code in maritime transportation, there are mostly used the ISO series containers having a width of 2438 mm. Containers with a height of 2438 mm have designations 1C, 1B, 1A, 1D; containers with a height of 2591 mm - 1CC, 1BB, 1AA; containers with a height of 2896 mm - 1BBB, 1AAA; and containers with a height less than 2438 mm have designations - 1CX, 1BX, 1AX and 1DX.

According to ISO standards, tank-containers are divided into a number of classes, the most common of which is IMO class 1 - for transportation of dangerous chemical goods.

Fastening the tank to the frame elements or supporting elements of container must withstand the inertia forces of the tank itself and its load, arising during the movement of vehicle.

To prevent an increase in the internal pressure, each tank or compartment is equipped with the pressure control devices. If necessary, tanks are insulated, and also, there may be installed the means of cargo heating or cooling. This includes the measures to ensure safety of tank and its contents in the event of an excessive rise in temperature and stresses.

3. Conclusion

Today, in international practice, the use of tank-containers having a number of design features (for example, small capacity for transportation of viscous chemical goods, with a special inner lining for transportation of acids and hydrogen peroxide), refrigerated, heated for high-melting bituminous products, as well as for bulk and powder cargo.

The general requirements for the design and operation of tank-containers for maritime transportation are as follows [3]:

- The bodies of tank-containers should be made of metal suitable for profiling. For the welded bodies, it is allowed to use only material whose weldability has been fully proven. Seams must be performed in a workmanlike manner; they are required to ensure complete safety. Materials for the tank must be suitable for environmental conditions during transportation, including the marine environment.
- Use of aluminum as a construction material should be restricted for tank-containers intended for land transport, but its use is allowed for maritime transport if there is a special permit on Part II of the UN Recommendations for certain goods.
- The coating of each tank, nozzles and pipelines must be continuous and must cover the surface of any flange. The coating material should not be significantly affected by contents, be homogeneous, non-porous, and be no less plastic than material of the pipelines of tank, and should have the same coefficients of thermal expansion.
- Tank materials, including any devices, gaskets and equipment, must not be exposed to the harmful effects of contents.
- Tank-containers should be designed and manufactured with a frame that provides reliable support during transportation, as well as with the appropriate lifting and fastening device.
- Tank-containers for dangerous goods of classes from 3 to 9 must be designed and manufactured so as to withstand a test pressure exceeding at least 1.5 times the maximum allowable working pressure. However, the test pressure should never be less than 150 kPa (1.5 bar).

Tank-containers without a vacuum safety valve must be designed in such a way as to withstand, without permanent deformation, the external pressure exceeding at least 40 kPa (0.4 bar) the internal pressure. Tanks equipped with a vacuum safety valve must be designed to withstand, without permanent deformation, an external pressure greater than the internal pressure by 21 kPa (0.21 bar) or more; the valve must be adjusted to operate at a gauge pressure of -21 kPa (-0.21 bar).

Abstract: The volume of trade between East and West of the Eurasian continent takes place on the numerous routes. However, the Europe-Caucasus-Asia (TRACECA) transport corridor is most known to the world community.

The TRACECA program projects involve the integrated development of sea, railway and road transport. As the consolidating measures, the central concern is the unification of transport legislation of the participating countries, the liberalization of regulation of shared services, the solution of common market and social problems in the area of the environment, security and international integration.

Time of delivery, as well as transportation costs through the Europe-Caucasus-Asia corridor depend upon the successful solution of these challenges.

KEY WORDS: RAIL FERRY CROSSING, MULTIMODAL TRANSPORTATION, LOGISTICAL SUPPORT.

1. Introduction

All transit routes that provide traffic flows by land, maritime and in the mixed form, play a crucial role in trade and economic relations between Europe and Asia. Over 50% of world traffic flows goes to the carriage of goods between West and East. Georgia is located in the most important and sensitive geopolitical regions of the world, in key location of the Great Silk Road that historically played a huge role in the development and relations of Europe and Asia. Since late last century, due to its own geographical space, historical past, political significance and economic capacity, Georgia has become a new geo-economic center between Europe and Asia, as well as between Russia and the Middle East. Consequently, a growing interest has emerged in Georgia as a new center of geo-economic attractiveness in regional and international arenas. The main geopolitical task of the country is integration into the European structures. Thus, the geopolitical strategy is clearly declared, and for the creation a niche for itself in the world economy, of utmost importance is to formulate and implement a well-constructed geo-economic strategy in relevant cooperation with local and international allies in the region. Thus, Georgia's geo-economic positions are influenced by: the interregional level players (Armenia, Azerbaijan); in the case of the interregional level - Russia, Turkey, Iran, Central Asia countries; and such international level players as the EU, the United States and China.

At the current stage, in the context of globalization, the geo-economic role of Georgia, as a significant transit artery linking the west and the east, north and south, becomes all the more relevant and takes place in the geo-economic interests of big countries, such as the USA, EU member states, China and neighboring states. This transit artery is also important for the economic interests of Central Asia countries. Thus, the geo-economic positioning of Georgia has turned Georgia into a global interest. The developed countries have started to actively cooperate with Georgia in order to maximize their advantageous geo-economic significance.

In the center of the Caucasus transport corridor, the railway line running through the territory of Azerbaijan and Georgia connects the port of Baku in the Caspian Sea with the Black Sea harbors in Batumi and Poti. Not so long ago, this line could pass 40 pairs of trains per day, was considered well-equipped and electrified. However, the modernity has demanded reconstruction of this and other rail routes. For example, Azerbaijan, on the basis of free technical and financial assistance from Europeans, was able to repair and reconstruct two large bridges on the state railway, carry out major repairs of the track in some sections, as well as to buy boiler installations for steam cleaning oil tankers, purchase spare parts and so on. Within a short period, the country also succeeded in creating its own base for major repairs of locomotives, freight and passenger stocks.

Some projects are based on foreign loans. In Azerbaijan, over $ 20 million from funds at the European Bank for Reconstruction and Development was used for reconstruction of the railway infrastructure, and in Georgia, the refurbishment of railways and roads was carried out within the World Bank project ($ 11 million).

In order to ensure the reliable transmission of information on the transportation of goods, the fiber-optic cable was laid along the Baku-Tbilisi-Poti-Batumi railway. The work was carried out under the TRACECA program, and $ 15 million was spent on it.

2. Preconditions and means for resolving the problem

On the Caspian, one of the most important transport hubs of the route is the Baku International Sea Port. It has several mechanized berths that specialize in working the cargo and tank vessels, as well as ferries and high-capacity containers. With the aid of the grant, the port has purchased the modern cargo-handling equipment. Rehabilitation of port using foreign investment is under way.

In the east, within the TRACECA projects, the great bulk of the cargo from Baku was to be transported by ferry across the Caspian Sea to the far bank into the port of Turkmenbashi. Then, the goods were to be transported through Turkmenistan by rail or motor road. In recent years, humanitarian aid and goods have gone on this route for economic recovery of Afghanistan. However, the peculiar position of the leadership of this country in relation to the transportation of goods, and the unpredictability of its position have generally forced to search for alternative routes. This has become the route of the north-east direction towards a new and rapidly developing Kazakh port of Aktau. It was rehabilitated in a short time with funds from EU, and this made it possible to significantly increase the volume of cargo and passenger traffic through the territory of Kazakhstan.

In the west, the Caucasian transport corridor is also divided into the separate directions. The railway ferry service linked the Georgian port of Poti to the Ukrainian port of Ilyichevsk and the Bulgarian port of Varna. The European Union had to spend the TRACECA program, and $ 13 million euros on the creation of a triple railway ferry link Varna-Ilyichevsk-Poti / Batumi.

With increased cargo traffic, it is possible to open railway ferry link to another Bulgarian port - Bourgas. Both Bulgarian ports are well equipped, and they can receive and store the increasing volumes of cargo, are linked by rail and motor roads to the most important business centers of Europe.

According to the tripartite agreement between Bulgaria, Georgia and Ukraine, the goods passing through their ports were dispensed from paying the state duty.

The absence of a railway line to the east from Batumi and Poti through Iran increases the importance of the motor road going in the same direction and not crossing Azerbaijan and Turkey. A project was proposed to transform the Armenian section of this road into a highway. Thanks to flattening, the length of the road will be noticeably reduced.

Azerbaijan and Georgia are also engaged in improving their roads. The idea was put forward to build a toll Transcaucasion highway Tbilisi-Baku, which will allow for reducing significantly travel times from the Black Sea coast to the Caspian Sea.
Georgia has access to Europe by land and sea routes. The land route is part of the Trans-Caspian international transport route (the middle corridor in Fig.1.). This route combines the Baku-Tbilisi-Kars railway with the Yavuz Sultan Selim bridge over the Bosphorus Strait. The Baku-Tbilisi-Kars railway is a transport corridor linking the railway networks of Azerbaijan, Georgia and Turkey. It was opened on October 30, 2017. The projected traffic for this route is 10 million tons, with a possible (theoretical) increase up to 20 million tons [1]. The sea route can serve as a way out to Europe through the Black Sea ports in Batumi, Poti and Anaklia. Currently, there are three ports in Georgia: Batumi, Poti and Kulevi. There is also a cargo terminal with liquid in Supsa. However, the depth of the existing ports is insufficient to receive medium-sized cargo ships or large carriers of crude oil. To deal this constraint, the government of Georgia has decided to build a deep-water port on the Black Sea coast in Anaklia. The depth of the seaport is 20.5 meters (in Batumi - 14 meters, in Poti - 8.5 meters). The port of Anaklia will be able to receive large-sized ships of the Panamax and Postpanamax classes with a loading capacity of 50–150 thousand tons [2]. It is expected that the new port will become one of the main logistics centers in the South Caucasus and one of the main sea gateways for Georgia. The expected throughput of the port should reach 100 million tons per year [2].

Petroleum pipelines Baku-Tbilisi-Ceyhan and Baku-Tbilisi-Supsa, as well as gas pipeline Baku-Tbilisi-Erzerum are routed via Georgia, and Georgia is active in TRACECA (Transport Corridor Europe Caucasus–Asia) and INOGATE (Interstate Oil and Gas Transportation to Europe) projects.

TRACECA is a program of international cooperation between the European Union and the partner countries on the organization of the Europe-Caucasus-Asia transport corridor. An important role in TRACECA is played by Georgian Railway JSC, which transports both liquid and dry cargo. Liquid cargo, consisting of crude oil and petroleum products, amounted to 46% of total goods traffic in 2016, while transit shipment - about 52% [3]. INOGATE is a program of international cooperation in the energy sector between the European Union, the Black Sea and Caspian states, as well as with their neighboring countries. The program was founded in 1996, and it is being implemented on behalf of the European Union [4]. For these pipelines and programs, an appropriate infrastructure has already been created, which can be used for the Belt and Road initiative.

Georgia has the free trade agreements with both EU and China. The Free Trade Agreement, signed in May 2015 in Beijing, entered into force on January 1, 2018. Prior to that, in 2014, the Deep and Comprehensive Free Trade Agreement (DCFTA) was signed between the European Union and Georgia, which has been entered into force since 2016 [14]. Georgia has also signed a Free Trade Agreement with Hong Kong. This Agreement was mutually agreed in 2016, and it has several standard components, particularly: elimination or reduction of tariffs; liberalization of non-tariff barriers; flexibility regarding the rules of origin to facilitate bilateral trade; procedures for simplifying customs procedures; investment liberalization, promotion and protection; liberalization of trade in services and the dispute settlement mechanism for a free-zone trade [5].

In recent years, the bilateral relations between Georgia and China have made rapid progress and obtained the positive results. Georgia positively considers the Belt and Road initiative, and wants to strengthen the cooperation with China in various fields.

3. Conclusion
The analysis of the main challenges and development opportunities of transport and logistics in Georgia indicate the need for developing a single state strategy and a single legal regulatory mechanism in this field, within which, it will be possible to demonstrate the capacities of the overall transport logistics system. In addition, full implementation of the transport and logistics potential of Georgia is associated with the analysis of the following issues in a common format: raising the quality of coordination between the individual government agencies; contribution to the development of a competitive environment among the carrier business operators; facilitating the implementation of a common tariff policy on cargo traffic; amendments to be implemented in the tax and free industrial zones regulatory legislation in Georgia; activating economic diplomacy; improving the administrative, technological and information space of transport and logistics infrastructure and services. The Belt and Road initiative contributes to the economic development of many countries. Georgia expects that this initiative will lead to an increase in transit shipments and a remarkable recovery of the national economy. In general, the Belt and Road initiative is beneficial both to Georgia and China. In this context, the governments of both countries should make every effort to further deepen their cooperation. Georgia has a chance to serve as a

Abstract: Due to the small and strictly organized space of a train car, the internal dimensions offer limited possibilities to redesign and extend the luggage storage space in order to accommodate a larger baggage. In order to have easy access and to be user friendly, the aim of this paper is to design an external baggage storage system for passenger trains. The system proposed, has a chain transmission and it is designed to accommodate the biggest size luggage commercially available.

Keywords: LUGGAGE STORAGE, TRANSPORT SERVICE, DESIGN

1. Introduction

Railway passenger transport ensures the movement of passengers and their luggage, with a higher degree of safety. It is done day and night and is carried out in a predefined schedule system. This study is focused on an innovative luggage storage system which can be a new direction for the railway industry, applicable to other means of public transport. A solution to rethink the luggage storage inside the wagon is presented in this paper. The possibility of relocating the space storage outside of the wagon, refers to the development of a modular design. This can solve the deficiencies of storage spaces without affecting the operation of the train and without making important structural changes to the wagons.

An analysis has been done based on passanger-baggage relationship on how to use the luggage storage space. Depending of the nature of the goods transported by passengers, the design of the wagon and the storage space has its limits.

2. Innovative luggage storage system description

The basic problems faced by the passanger while carrying a luggage inside and outside the train are the following [1]: low or non-existent storage space (number and size of luggages, placing luggage under the seat) (figure 1a); climbing and descending on stairs with hand luggage [2]; difficulty to perform basic movements inside the wagon with the luggage in the hand due to width aisle of only 60 cm (figure 1b)[3]; the lack of an adequate security system; the presence of many pieces of luggage in the interior reduces movement (figure 1b); damage of luggages due to inappropriate transport (figure 2a) and to inappropriately handled (figure 2 b).

Rail infrastructure is regulated by rigid safety requirements and European standards. Due to this fact, this paper proposes two solutions for extended luggage storage without altering the wagon configuration. The first solution is a module that can be attached to the wagon (Figure 3a). The second one, is placing the module in another wagon especially designed only for luggage (figure 3b).

Fig. 3 a) modulus that can be attached; b) wagon especially designed only for luggage

In order to devise a new storage system an algorithm was developed to take into account all variables (figure 4).

Fig. 4 Algorithm for designing a new luggage storage system

The analysis of the interior of the wagons and the general configuration of the train leads to an optimal solution to place the storage system modulus outside of the wagon. Thus, it becomes a component that can be adaptable to different types of wagons.

The positioning of the storage system modulus outside the train was designed in compliance with the standards of the maximum permissible gauge on the railway tracks (figura 5) [4]. Also elements of morphology and functionality, passenger interaction
solutions were taken into account, resulting in a proposal that complies with the safety requirements imposed by the standardized passenger carriage system. The proposed solution is a fixed, modular structure that can be attached to the ends of the train wagons, making a common body with the wagon. The development of such storage space is only allowed on the longitudinal axis of the train. The positioning of the modulus can be seen in figure 6.

![Fig. 5 Standards dimensions for train wagons](image)

The storage modulus is composed of a metal structure frame and capsules where the luggage can be placed (figures 7). In figure 8 b can be seen how the metal frame of the modulus is positioned on the wagon. This type of structure permits the existence of a passage lane thought the storage modulus, allowing the movement between wagons (figure 8a).

![Fig. 7 a) metal structure frame; b) metal structure frame with storage capsules](image)

The closing and opening system of the storage capsule provides user access on both sides, depending on the position of the train to the platform and consists of three elements: the frame that provides the clamping of the module transport system, a drawer that can slide 50% on the outside, on both sides and the door which in the open position forms a ramp to be able to place the luggage more easily into the capsule.

![Fig. 8, a) Passage lane through the luggage storage module; b) Module coupling system, common to the wagon](image)

3. Optimisation of the luggage storage system

The capsule system is developed in parallel with the structure of the module influencing each other in terms of morphology and functioning mechanics.

This has led to dimensioning the module around the capsule gauge. For the construction of such a product, a material with special properties is required which can withstand stress, vibration, wear due to the loading and unloading of other products of different density, weight and roughness, temperature changes depending on the season, maintenance and the level of complexity for manufacturing [5]. As a material, polycarbonate meets the requirements so is the optimal choice due to its unique properties [6].

The shape of the storage capsule results from the standard baggage dimensions and the need for a required space, circulation inside the module and end-user relationship. Due to the standard market size of luggage, influenced by railways' rules, the capsule had to adopt the highest standard size for accommodating all types of luggage. The functional model of the capsule was determined by the analysis of the movement space inside the module and the need to be accessed on both sides by the user. The material chosen for the construction of this capsule is also polycarbonate with outstanding strength, low weight, ease of manufacture and maintenance and low wear due to repeated luggage storage [7].
The outer shell protects the capsules and the entire inner mechanism from the outside (figure 10 b). On this cover are mounted vertical sliding doors (figure 10 b) when the train is stationary. Thus permitting access to the capsules and barcode scanner which will forward the information to the requested capsule.

The clamping system used to fix the outer shell does not involve major structural changes for the wagons, retaining the same type of standard coupling and a simple solution for mounting the module (Figure 10 a).

Thus, the module represents an attachment that can be dismantled if there is no need to use it, without the wagon requiring modifications to be put back into operation as a result of the module removal.

4. Conclusions

The design concept is a viable solution that aims to solve, even partially, the issues raised based on user-baggage relationship on how to use the luggage storage space.

The new storage system, in the given context, provides adequate space for storage, easy access and independent use without auxiliary staff.

The proposed system brings added comfort to passenger rail transportation. The luggage storage system fluidizes passenger traffic by allowing them to climb and descend more easily. The proposed module offers a high level of safety for passengers due to the innovative luggage storage system.

marilena.stoica@upb.ro

Abstract: An innovative external baggage storage system for public transportation has been developed to ensure the ergonomic requirements. This paper proposes, for this system, a user interface that increases the level of comfort and security for train passengers. The interaction between the storage system and the final user is based on a complex scenario which includes the analysis of train stops time frames, type of luggage, train station configuration and the user’s age.

Keywords: PUBLIC TRANSPORTATION, STORAGE SYSTEM, ERGONOMIC, USER INTERFACE

1. Introduction

The purpose of this study is to analyze the current state of comfort and accessibility in public transport by rail and how they interfere with passenger transport options and their comfort when using these services. This study is based on surveys conducted in Europe by various companies specialized in this field and on statistical data recorded during simulations of passenger behavior and time tables on various train routes in Romania in the last 3 years by studying [1].

The study shows that there are various situations in Europe in terms of passenger comfort, accessibility and security, and areas requiring improvements in rail transport services.

These surveys concluded that the major difficulties are embarkation in train, finding the reserved place, access to storage spaces, reduced mobility inside trains, uncomfortable chairs and the lack of security system.

The research is focused on the study of elderly people, people with disabilities and tourists. The results of this work will be relevant to future development and design, in terms of ergonomics, accessibility and comfort, in the public transport area. This study is aiming to optimize the flow between the passenger and luggage module by using the same user interface.

A major concern in rail passenger services is to find and assess the level of customer satisfaction. This level of satisfaction is largely influenced by the following factors: comfort, accessibility and security. Although these factors have been improved over the past 20 years, there are still major problems that require resolution and situations requiring improvement (figure 1), according to the information presented in the following study.

The impact of passenger dissatisfaction with rail transport services can lead to operational and financial costs. Also, this can impact environment in terms of people preferring to use personal transportation (greater pollution and more congested roads) [2].

In this study, the time required for different types of passengers to embark and disembark from the train is measured. Passengers aged between 15 to 70 years with heavy or light luggage are considered. Data was also collected during several train journeys, with a large baggage experimenting with the storage solutions offered inside the train [3].

2. Ergonomic environment

The comfort or discomfort of train passengers vary according to the purpose of the journey, the age of the passengers, the type of the wagon and the length of the journey. The influence of these factors increases when agglomeration exceeds a certain level, due to inadequate baggage storage or exceeding the normal journey capacity.

Human behavior has a special role in a properly constructed ergonomic environment. Psychological, behavioral and physical factors are needed to be analyzed in order to determine their influence on passenger comfort. Ethnographic methods can also be used to understand passengers behavior so that the user does not feel constrained in any way when traveling.

The constant changing technology can be used to inform, influence and direct passengers to make better use of the solutions offered for travel. Besides that, it is very important how the design impacts passenger behavior.

To determine the efficiency of accessibility and ergonomics offered by the train’s characteristics in relation to human behavior, the time required for different passengers for boarding and disembarking from the train was measured [4]. The time measurement process was carried out during various hours of the day, including peak hours. By analyzing these times, adjustments can be made to the access routes and inside the train to achieve a better flow of passengers during the embarkation and disembarkation process.

A wide range of metal powders (from light alloys through steels to super-alloys and composites) is currently available for DMLS
process and other new materials are under development. Table 1 lists mechanical properties of selected powder materials.

![Fig. 3 Time analysis for disembarkation](image)

Thus, in case of medium and large luggage, the average disembarkation time for people aged from 20 to 35 was 4.54 seconds and for embarkation was 4.91 seconds. For the same type of luggage, the average time at disembarkation for people between 35-70 years was 8.4 seconds, and 8.8 seconds for embarkation. For younger people, boarding or disembarking time was about 2.5 seconds and for the elderly, between 7 and 15 seconds, depending on their luggage.

Figure 2 and 3 shows disembarkation and boarding times in function of luggage volume for people of different ages was analysed considering stationary times at different stops. An increase in average time can be observed (highlighted in blue) for boarding and disembarking in case of people with large luggage and the elderly (respective of the size of their luggage).

3. User interface

The interaction between the user and the module is based on a complex scenario. The module is mounted on a train wagon and there is a live communication interface with the railway service provider. The scenario takes into account stationary times, the type of baggage and user age.

The user has access to a deposit space in the moment of buying the ticket. This will probably require an additional cost (figure 4).

![Fig. 4 Scenario: First step- Purchasing the ticket for deposit space](image)

The allocation of a deposit space is done by a software. This software process the availability of spaces and destination stations. Boundaries are put in place, to avoid overloading a module, using methods to uniform the distributing of the seats for the entire train wagon.

Access to the deposit space is possible by scanning the barcode printed on the ticket at the time of purchase (figure 5). The ticket scan sends a command to the module to select the allocated deposit space [5], bringing it to the level of the user (figure 6).

![Fig. 5 Scenario: Second step- Automatically assignment of deposit space](image)

The system takes the capsule with the luggage in, then prepares another capsule for the next user (figure 6).

To access the baggage at the destination station, the user has to scan the ticket on a device located inside the wagon in the immediate vicinity of the access door (figure 7). The location of the scanning device, is based on the intention of organizing and fluidizing access to the module. The time required for pick up the luggage from the deposit space is equivalent with the time needed for the passenger to scan the ticket, disembark the train and arrive in front of the module.

![Fig. 6 Scenario: Third step- System pick up of the luggage.](image)

![Fig. 7 Scenario: Fourth step- Pick up the luggage at destination.](image)

4. Conclusions

The external baggage storage system presented in this paper brings an increase in comfort and security for railway transportation users. The system offers adequate storage for luggage and easy access.

The storage dimensions are in total concordance with the existing type of baggage. The module dimensions permit the internal design, to be modified in case of changing the international standards.

Implementation of this system doesn’t require administrative staff and has a friendly user interface. Also, the system pick up mechanism it’s easy to use, by elderly and people with disabilities.

From a security point of view, the system can be improved, by adding special scanning device in the moment of the pick up.

The proposed concept represent a viable solution which can partially resolve some of the current shortcomings in public transportation.

NEW VEHICLES AS OUR REALITY

Prof dr Nataša Tomić-Petrović, University of Belgrade, Serbia

Abstract: The world is changing very fast. The future already arrived in industry. Europe and China expelled classic automobiles and replace them with electrical. European Union predicts that till 2020 they will have 3,5 million electric cars and 800,000 stations for its filling. In Serbia according to the Ministry of Internal Affairs from 2011. only 114 vehicles on electric power and 90 hybrids were registered.

The introduction of vehicles without a driver on the roads of the world will happen faster than lawmakers predicted. Recently, the countries began to discuss laws regulating autonomous vehicles, but only a few of them actually adopted such laws. California, Nevada, Michigan and Florida (USA) allow autonomous cars on the road, while their use on public roads in the states that have not enacted laws is neither illegal, nor specifically allowed.

Experts warn that it could take decades before legislators permit the production of vehicles without manual commands and it is possible that during the transitional period when conventional and vehicles without a driver would share the road, security really could be worse. In order to get a vehicle permit, with robots and electronics in them must also stand the man, as well as the system which in the case of emergency enables taking control by man.

The first passenger drone in the world that can independently carry one person by air got permission for testing in Nevada. In the race entered the Chinese, and the first flying car could have its first drive as soon as next year 2020. The Chinese company “Ehang” still in 2016 presented the model of unmanned aerial vehicle that can carry one person 30 kilometers by speed of 100 km/h. The “Airbus” vision of taxi that solves the problem of traffic jam by throwing away of wheels at a special station and hooking on for the roof the massive drone, to pick it up in the air at the critical moment, was presented.

Expectations are that in this type of traffic the number of accidents would decrease for at least 90%, what would save thousands of human lives, while those who due to some limitations are not able to drive a car would not be discriminated, but could use self-driving vehicles like everybody else.

KEYWORDS: AUTOMOBILES, LAW, WORLD, FUTURE, SERBIA

Introduction

In the 18th century, on the streets of the metropolis appeared vehicles using steam. The first vehicle driven on this drive in Paris was constructed by the French explorer Nicholas Joseph Kinjo. As the creator of the modern version of the car is considered the inventor Karl Benz from Mannheim, who was the first who sold in 1880 the vehicle that was working by its own power. Not until the last decade of the 19th century the car with four wheels was created.

There is a remarkable technology progress in the world, so it is believed that by 2025 robots will take over more than half of the jobs. The development of technology, automation and artificial intelligence can cause a loss of 75 million jobs by 2022, but also the creation of 133 million new job positions, according to a report titled “The Future of jobs in 2018”. The world is changing very fast. The future already arrived in industry. Europe and China expelled classic automobiles and replace them with electrical. European Union predicts that till 2020 they will have 3,5 million electric cars and 800,000 stations for its filling. In Serbia according to the Ministry of Internal Affairs from 2011. only 114 vehicles on electric power and 90 hybrids were registered.

Vehicles for the future – World experience

The homeland of the first modern electrical car is Greece. Today in Europe for example, BMW has unveiled a redesigned “series 7” and completely new look of the vehicle was obtained. For a long time, “series 7” is the bestseller on the Chinese market. After versions for Chinese and the US market “Volkswagen” has shown also refreshed “Passat” (B 8), continuing the life of the eighth generation of this popular model. It is planned that from May 2019 it will be offered to drivers, and it will be using the new technology that allows partially autonomous driving up to the speed of 210 kilometer/h. This car was first presented in March on the Salon in Genève. While the production of the new “Skoda” cars began, company “Volvo” has announced a recall of 167,000 of its automobiles. With the “Volvo” there was a long list of producers who will not appear on the Motor Show in Geneva ("Ford", "Opel", "Hyundai", "Land Rover Jaguar").

The introduction of vehicles without a driver on the roads of the world will happen faster than lawmakers predicted. Recently, the countries began to discuss laws regulating autonomous vehicles, but only a few of them actually adopted such laws. California, Nevada, Michigan and Florida (USA) allow autonomous cars on the road, while their use on public roads in the states that have not enacted laws is neither illegal, nor specifically allowed.

In 1999 Gehring et al. formulated that the autonomous car (car without driver, self-driving car, robot car) is the vehicle that is able to sense its environment and run without contribution of the driver.1 There are more degrees of autonomy of self-driving vehicles (Wood et al. 2012).

Experts warn that it could take decades before legislators permit the production of vehicles without manual commands and it is possible that during the transitional period when conventional and vehicles without a driver would share the road, security really could be worse. In order to get a vehicle permit, with robots and electronics in them must also stand the man, as well as the system which in the case of emergency enables taking control by man.

Since 2018, “Deutsche Bahn” that founded the branch “Joki” dedicated to electric mobility and the transport of the future, intends to test its station wagon in several German cities. Testing was conducted in the spa Bad Birnbach, in Bavaria in southern Germany, and this electric mini bus can carry 12 passengers and this is a new era of public transportation.

For the next year “Mercedes” announces the first self-driving vehicle, so driving licenses will not be required. During last year 1.3 million of these cars were sold in the world.

It is interesting that in 2018 /in April / US giant “Ford” ceased to produce passenger cars in its plants in North America. US factory produces only one old model, and it is focused on trucks and SUVs. There is no sentimentality in business! However one model maintained its position (while these models are not: "Fiesta", “Taurus”, “Galaxy”, “Fairline”, etc.) ... that is the famous "Mustang".2 It survived all the cuts, the oil crisis of the seventies, the transition to the SUV. It’s been 54 years since the first "Mustang" came from the production line - then this model was presented as an alternative to expensive European sports cars. They say “Mustang" represents freedom.

1 It is a motor vehicle that uses artificial intelligence, coordinates and sensors of the global positioning system GPS /Global Positioning System/ for driving without active intervention of the driver.

2 At various tests this car is still passes better than "Porsche" 911. During the year 2017, "Ford" has sold 126,000 in even 146 countries. That was the best-selling sports car in the world.
At the Paris Motor Show opened on the 5th of October 2018, the 120 years of its existence was marked, and all domestic producers were present ("Renault", "Citroen", "Peugeot") as well as "Mercedes-Benz", "BMW", while many important manufacturers were absent. The French are planning to present 8 new electric cars (record holder is the model "zoe") and, soon the EV version of the "Quid", a small SUV that is sold on developing markets should join) before year 2022.

Japanese “Nissan” decided made a decision to abandon production new generation of its model “X-Trail” in England, due to the uncertainty related to Brexit. New model will be produced only in Japan.

In early 2019, at the Consumer Electronics Show in Las Vegas "Mercedes" introduced a new generation of models, "CLA". This small limousine the German manufacturer is now longer, wider and lower than the previous one. This new generation of the "CLA" model inherited all the best from the A and B class (new digital instrument panel with two touch screen, and the drivers are also offered seats with massage and cooling functions). At the fair "CLA 250" is exposed, while the top version should be "Mercedes CLA 45"). The price has not yet been announced to the public.

It is significant that more and more manufacturers are turning to modern technology and that the end of 2018 was marked by hybrids. "Subaru" represented "kroster plug-in hybrid," and "Honda" hybrid version of the model CR-V. Legend says that every seven days somewhere in the world appears new SUV, popular urban SUV. At the Fair in Los Angeles at the end of November 2018 was presented a hybrid version of the "krostrrek", which will use innovative technology "Star drive" that integrates an electric motor, all-wheel drive, build-in lithium ion battery that offers a range of only 27 kilometers (braking is regenerative, so the braking energy is used for charging the battery, as well as on other models).

**Smart Mobility in the World**

Currently, at least 19 companies are working on the flying cars, especially big ones like "Boeing" and "Airbus". We hope that this idea will become a reality.

The first passenger drone in the world that can independently carry one person by air got permission for testing in Nevada. In the race entered the Chinese, and the first flying car could have its first drive as soon as next year 2020. The Chinese company "Ehang" still in 2016 presented the model of unmanned aerial vehicle that can carry one person 30 kilometers by speed of 100 km/h. The "Airbus" vision of taxi that solves the problem of traffic jam by throwing away of wheels at a special station and hooking on for the roof the massive drone, to pick it up in the air at the critical moment, was presented.

On the Fair in Las Vegas, in January 2019, the drone "Ehang 184" was presented. The most notable at the show in Las Vegas was "Bel nexus" with the hybrid system as the futuristic vehicle. The drone at the fair in Las Vegas thrilled the representatives of one biotechnological company, which announced the collaboration with "Ehang" in order to adapt the vehicle for transportation of organs for transplantation. "Ehang" is hoping to start testing this year. State of Nevada was one of the first states to permit testing of driverless cars. Last five years, Nevada has become the testing ground for advanced means of transport. It is one of the first American states which have allowed test driving of cars without a driver on public roads.

"Google" car does that running on the roads - with no driver at the wheel. The idea is that the passenger simply enters the destination on the screen (diagonal of 30 cm), a drone does everything else, from navigation to communication with flight control. It would fly at the altitudes of up to 3.5 kilometers, at speed up to 100 kilometers per hour, using eight propellers on four knobs. The maximum flight length is currently 23 minutes.

However, since the completely autonomous land vehicles probably will not be widely available until the middle of next decade, we should not expect in the near future a taxi drones. "EHang" is hoping the testing of their taxi drone will be the first step in making the technology available to the masses. It’s an innovative jump in drone technology.

At the time of law of obligations codification, special rules were set out concerning the responsibility of the state. Rules are also regulating causes of damage and compensation. The question is how long will it take to get a report on the accident and what will be the costs if the investigation takes months?

The “flying car” was produced in “Boeing” to ensure that passengers can fly over the street jam, successfully passed all the tests, but the question is whether this will be the mean of transport of the future. Fully autonomous prototype successfully passed testing in the State of Virginia. For only one year, from concept to flying model was passed the right way. In just one year the road from concept to flying model was covered. The vehicle is electric, and the idea is to fly on its own, without a pilot. The length of the route for transportation of passengers will amount to 80 kilometers. Almost all aviation companies compete in this production and by the newest information the flying car should start with transportation of passengers already from 2020.

**News from Serbia**

Serbia has made great progress in the area of digitalization, which is a great chance to be more efficient, with the motto "Proudly made in Serbia". New chance could be a new model “Fiat Gardiniara” that will be produced in the factory in Kragujevac in Serbia. Along with the classic version of this car in Kragujevac will also begin the production of hybrid version of "Fiat 500”.

New industrial politics, the 4th industrial revolution which meant development of the new technologies, digitalization, production automation, smart factories and buildings, the development of energy storage systems and advanced IT technologies the future development of Serbia is based on. These are our strategic aims and especially the development of the infrastructural network (railway infra-structure and development of the new railroad tracks Belgrade, Serbia – Budapest, Hungary) is of the great importance. This fast railroad tracks should be open by 2023, with 60 road crossings what will significantly increase the level of security and the maximal speed of train will be determined by the computer at every moment.

We know that fulfilling the promises is difficult, but in these conditions - possible.

On the highway from the capital town Belgrade to Niš were placed 56 cameras for those who escape from paying the toll or exceed the prescribed speed. Public Enterprise "Roads of Serbia" wants to increase the scope of toll payment from 99.92 to 100% and so prevent arrogant drivers to break down fences and exit the highway – Budapet, Hungary) is of the great importance. This fast railroad tracks should be open by 2023, with 60 road crossings what will significantly increase the level of security and the maximal speed of train will be determined by the computer at every moment.

We know that fulfilling the promises is difficult, but in these conditions - possible.

On the highway from the capital town Belgrade to Niš were placed 56 cameras for those who escape from paying the toll or exceed the prescribed speed. Public Enterprise “Roads of Serbia” wants to increase the scope of toll payment from 99.92 to 100% and so prevent arrogant drivers to break down fences and exit the highway. 

News from Serbia

Serbia has made great progress in the area of digitalization, which is a great chance to be more efficient, with the motto “Proudly made in Serbia”. New chance could be a new model “Fiat Gardiniara” that will be produced in the factory in Kragujevac in Serbia. Along with the classic version of this car in Kragujevac will also begin the production of hybrid version of “Fiat 500”.

New industrial politics, the 4th industrial revolution which meant development of the new technologies, digitalization, production automation, smart factories and buildings, the development of energy storage systems and advanced IT technologies the future development of Serbia is based on. These are our strategic aims and especially the development of the infrastructural network (railway infra-structure and development of the new railroad tracks Belgrade, Serbia – Budapest, Hungary) is of the great importance. This fast railroad tracks should be open by 2023, with 60 road crossings what will significantly increase the level of security and the maximal speed of train will be determined by the computer at every moment.

We know that fulfilling the promises is difficult, but in these conditions - possible.

On the highway from the capital town Belgrade to Niš were placed 56 cameras for those who escape from paying the toll or exceed the prescribed speed. Public Enterprise “Roads of Serbia” wants to increase the scope of toll payment from 99.92 to 100% and so prevent arrogant drivers to break down fences and exit the highway.

Programming was introduced as a compulsory subject in schools in Serbia.

An extended version of the “Fiat 500” with places for 5 passengers and a slightly larger luggage compartment.

The cameras will be placed at the 28 existing portals in both directions.
highway without authorization on so-called "wild exits", as well as the trucks that are overloaded more than it is allowed. The new method of control on the highway will have the subsystem for notification of drivers on the situation on the highway, toll stations, border crossings, stoppages, as well as meteorological conditions.

"Fiat" remains in Serbia and is preparing the new model of automobile "601". The future of this company will be insured in Serbia. In the sections of the factory in Kragujevac are already ready for serial production of the model "550-L" with hybrid power. The capacity of the factory in Kragujevac is more than 185.000 automobiles yearly. Till September 2018, only 2% of "Fiat's 500 L" quota was sold in Serbia and the rest in Europe and the United States.

With improved infrastructure and transport means Serbia would be able to compete with the traffic of European countries. It is a hybrid model with an electric motor. The new "B-SUV" would be produced in Kragujevac in parallel with the existing model "500 L". And in this 2019 year Belgrade, our capital will be a candidate for the green capital of Europe.

The World arrived in Belgrade in the period from 22 to 31st of March 2019 at the International Car Salon. It was one of the most attractive fairs in the last ten or more years. The market of new cars in Serbia is recovering, however, the number of premiers depends on the Salon in Geneva, and more novelties of hybrid and electric vehicles were confirmed. The main theme were electric vehicles and hybrids, and the scientific meeting on electromobility was organized too. There were 400 exhibitors from 30 countries, and 48 premiers at the exhibition.

Conclusion

Autonomous vehicles are considered to be the technology that will change the city, public and private transportation, as well as the concept of mobility in general. Besides the undisputed safer driving, autonomous vehicles would be lighter than the existing and would contribute to the reduction of average fuel consumption (if the petroleum products would still be used to drive these cars).

Automobile Association of the Journalists of Serbia proclaimed the "Peugeot 508" as the "Car of the year 2019". The best-selling car in the competition of hybrids during 2018 was the "Toyota", and the best-selling electric car "model Volkswagan AP".

The expansion of autonomous vehicles will depend on the belief of the public that are self-driving cars are considerably safer than those manually-controlled. Expectations are that in this type of traffic the number of accidents would decrease for at least 90%, what would save thousands of human lives, while those who due to some limitations are not able to drive a car would not be discriminated, but could use self-driving vehicles like everybody else.

References

10 Today we have the museum for old timers, in which among other exhibits there is also the one with motor of “Fiat” popular “Fića” constructed by domestic intellect in Rakovica (it did not achieve to make a way through serial production, but on tests it showed excellent performances, better than “Fiat’s” original). Many years ago our engineers M. Davidović, M.Popović and D. Koprivica completed bolide, little motor of 850 cubic meters that will reach speed of 160 km/h. Even to-day it is in excellent condition and they made it as a hobby. The whole Museum was made with love, old timers are today fixed up and all drivable. This Museum is today interesting and valuable place in the center of Belgrade.
Abstract: The development of strategies for mitigating negative environmental impacts has been developed for a long period of time and it is actually now also. At the European level, the DIRECTIVE 2014/94/EU of the European Parliament and of the Council has been adopted. This the Directive has been in force since 2014. The main objective of the Directive is to reduce the use of oil and the adverse effects caused by traffic, respectively the transition to alternative fuels. The idea of electric vehicles and their advantages is popularized because that. This work will highlight the need for the use of electric vehicles, as well as the development of strategies for their use. Many of the leading European and world countries already have a great deal of successful practice in sustainable development and can boast of positive results. These countries emphasize the need of using natural resources and transforming them into energy that can be used, while minimizing negative effects. Also, various innovations that influence the improvement of the quality of life and the possibilities of using electric vehicles are being developed and projected. How and to what extent electric cars and the use of alternative fuel can contribute to a better and cleaner environment has not yet been established, but it is certain that they can have a positive effect on the future.

Keywords: SUSTAINABLE MOBILITY, ELECTRIC CARS, CHARGING INFRASTRUCTURE

1. Introduction

A mobility of people and goods is necessary for a quality life, business competitiveness, economic and social development, both for developed and developing countries. On the other hand, increase of mobility caused increase of motorization, development of new transport infrastructure instead of green areas, increased traffic load, increased pollution, increased noise, and creation of many other negative effects on human society. Over time, negative effects were increasing to such an extent that it was necessary find ways to mitigate them. The idea of sustainable mobility which essentially emphasized the importance of transport as an economic activity, has developed at the global level. This idea was emphasizing that traffic safety, environmental protection, better and economically more profitable transport should be addressed. Many countries began to develop strategies and offer different solutions with this goal in the 20th century. One of the solutions, in an aspiration of sustainable development, was transition to alternative fuel, because use of oil began to exceed limits of supply capability. As a result, the idea of electric vehicles and advantages offers is popularized.

Electric vehicles are a mode of transport that can be considered sustainable and which is get an increasing role within strategies developed by many European and world countries. Electric vehicles offer great potential to dramatically reduce local air pollution, greenhouse gas emissions and resulting climate change impacts, and oil use from the transport sector [1].

In recent years, various strategies have been adopted with aim of identifying and reducing harmful causative agents in air, soil and water, and adjustments and harmonization of legislative policy have been made, both at national and international level. The modes of transport are potentiating who have equally positive influence on a living space and possibility of providing efficient service. Special emphasis is placed on reducing the use of conventional fuel and promoting renewable energy sources. Such a policy also involves encouraging and improving production of new vehicles that will use biofuels or some other less harmful energy sources.

3.1. Basic recommendations at the EU level

The negative consequences of mobility, that society faces, are most prominent in urban areas. Emission of harmful gases, energy consumption, communal noise, taking up space in favor of traffic infrastructure, etc. are just some of the consequences, which may be most often highlighted as adverse effects of traffic.

The emission of harmful gases is increasing every year, especially the amount of CO₂. The main source of CO₂ nascency is burning of fossil fuels and it is in principle contributes to greenhouse effect. According to the EU statistical data from 2011, traffic activities resulted in approximately 20% of total greenhouse gas emissions as a result of all activities (Figure 1). More than 70% of CO₂ is derived from road motor vehicles, observed in relation to the total amount of CO₂ generated from transport activities in EU countries. [3]

Consequently, the concept of sustainability has become present in all segments, as well as in the context of mobility, or transport. Today, there are a lot of talk about the concept of sustainable mobility. The transport is a key driver in attempts to increase the degree of sustainability in our societies. It has a direct effect on all the negative impacts that can be measured environmental impacts, social impacts, economic impacts, etc. Sustainable transport, or sustainable mobility, essentially implies a future vision of a society that will enable economic development and normal functioning of society, but in sustainable and acceptable frameworks.

Fig. 1 CO₂ transport emissions, as a result of different activities in EU, 2011 [3].
harmful to environment as well, the EU has adopted a Directive that seeks to encourages its members towards sustainable mobility and healthier life. Better knows as Directive 2014/94 / EU of the European Parliament and of the Council of 2014, this document provides guidance and suggests the use of alternative fuels and setting up of an infrastructure that will enable the supply of vehicles to alternative fuels.

EU Member States were obliged to adopt infrastructure construction plans for alternative fuels vehicles, where completion of construction is planned for 2020 and 2025 respectively, all depending on vehicles technologies. Within this strategy, electromobility has also an important place with all its specific recommendations are given regarding the development of charging infrastructure, promotion of technological innovations in this field, use of intelligent metering systems in order to contribute to stability of the electricity system by recharging batteries from the grid at times of low general electricity demand, etc. [4]

The European Commission also dealt with the reduction of pollution within the White Paper. They have introduced a strategy that generally predicted reduction in European dependence on oil imports and reduction in carbon emissions in the transport sector for 60%, by 2050. In addition, use of cleaner cars and cleaner fuels is envisaged for transport in urban areas. There is the plan that 50% of cars with conventional fuel are replaced by cleaner cars by 2030, and their complete abolition is done by 2050 [5]. Within the White Paper are presented construction infrastructure network guidelines, financing through various funds and other sources, adoption of new technologies (new technologies of traffic control, new technologies for filling vehicles - new charging stations), etc. During 2012, the European Commission has published a strategy for clean transport systems, with specific details on measures to encourage and facilitate introduction of clean vehicles and development of standards across the EU for the application of clean vehicles, with particular emphasis on electric vehicles.

CIVITAS Initiative, financed by EU, also plays a significant role in promoting and supporting cities which are introducing or considering introduction of a strategic policy for sustainable urban mobility. The Initiative started its work in 2002 launching the CIVITAS I project, which included 19 cities. Development of following projects also increased the number of participating cities, so today this number reached a figure of 60 cities [6]. Among other things, cities involved in the CIVITAS Initiative promote clean fuels and vehicles using alternative fuels, including electric vehicles.

As can be seen, previous experience shows that in Europe, and of course at the world level, different strategies are developed that result from today’s conditions and today’s real picture of state of the environment. Most of strategies are based on preserving natural environment, then maintaining human health and safety, meeting needs of population for travel, supporting a good and efficient economy, minimizing transport and infrastructure costs, maintaining energy security and ensuring long-term sustainability of the transport system. Within framework of strategies, measures are proposed that offer solutions and improvement of situation. Different directives and regulations have been adopted in the framework of international and national regulations, all with unique goal of promoting the sustainable mobility and the sustainable transport.

3. Experience of individual countries

All developed world countries are constantly working on developing strategies for the use of electric vehicles in accordance with their capabilities and policies. Countries are developing partnerships with companies involved in production of electric vehicles and development of their filling infrastructure, striving always with various innovations and improvements. Reviving concept of sustainable mobility through the development of electric vehicles and their infrastructure, is basically a costly investment. However, many years of experience and practice, cooperation with a clearly defined policy of functioning, can lead to fantastic results that are useful and profitable for producers, governments and consumers, and at same time there is a healthier environment.

United Kingdom

When it comes to electric vehicles and their infrastructure in the United Kingdom, it can be said that the British with great care and investment have dedicated themselves to this topic. There are approximately 212000 electric vehicles registered in the UK, from which 60000 were registered last year [7]. Research in the UK shows that all monthly electric vehicle related costs are approximate to costs required by conventional vehicles. Certain types of subsidies and tax deductions for electric vehicles are certainly contributed to this. The electric vehicles in the UK are free of toll payments. In the UK, most of the charging electric vehicles is done at home, with the government paying 75% of installation costs [8]. 11837 electric vehicle chargers were registered on 4237 public locations, of which 2173 were super fast chargers during 2017 [9].

The Highways England, the government organisation responsible for road infrastructure maintenance, develops a project that would allow enable to electric vehicles to be supplied with electricity during their movement. Need for this project has arisen due to lack of filling stations on highways, but also in order to maintain continuity in driving. The aim of the project is a select number of cars will be fitted with requisite wireless charging technology, and a test road will be built to show how smaller substations, AC/AC converters, and power transfer loops can provide inductive charging built into the road itself [10]. The UK Government has provided a great deal of money to try this technology with aim to create a more sustainable road network for England.

Another of the most interesting innovations the British have patented is electric busses. The testing of project was carried out in the city of Milton Keynes, on bus line 7. The length of the line is 25 km. Fleet of 8 electric vehicles was inserted on the line 7 and their testing is scheduled for the end of 2019. Since movement of vehicles on a public transport line is organized so that buses operate in a determined order of driving, it is very important to adjust filling of vehicle to their movement on the line. It is therefore necessary to use every little longer of their standing, which is usually at final terminals. The bus timetable is not disturbed by this way of charging which is an advantage of wireless charging.

Such a project has come up with positive reviews and there are intentions to expand and promote it in the future. Financial incentives for 11 new electric bus and charging infrastructure have been approved [11].

Fig. 2 Wireless charging of electric buses [12].
Germany

Germany is considered the leading country in production of cars. Many major manufacturers come from this country. However, the beginnings of development of idea about electric vehicles were not optimistic, especially since the Government declared that they would not provide subsidies. The Government has recognized many positive things about the use of electric vehicles by time, and they began to take part more and more in the promotion of electric vehicles. 129246 electric vehicles were registered in Germany, in 2017. Targets are targeted towards 2020, when hopes are made to increase the number of electric vehicles to as much as one million. The charging infrastructure is still in the process of development and progress. Germany owned 4800 public charging stations in 2014. All projects related to the development of the charging station network were realized on basis of partnership relations between car manufacturers and utility companies [13].

One of the main problems facing larger cities in Germany and other countries is problem with an electricity network that is not sufficiently equipped to support the development of electric vehicles. Electric vehicles require the use of electricity whose network is designed to meet conditions required by each city, but not overloading caused by the charging of electric vehicles. This automatically leads to the need to reconstruct the network in line with increase in the number of cars in order to avoid collapse and loss of electricity. Research in Germany has found that as much as 80% of electric vehicles are charged at home or at work, which represents a large energy consumption [14]. It is necessary to consider all possibilities and find the most adequate solution, since overall idea about the development of electric vehicles is the best option for the future. In Germany, the solution is sought through common cooperation between industry, government and society, in search of alternative sources of supply, such as solar energy.

Similar to the UK, in Germany, the city of Mannheim developed the idea of electric buses and their use in city traffic. A pilot project was carried out in 2013. The project involved introduction of two electric buses on line 63 in the Mannheim which can charging by wireless network on bus stops. This project was implemented for 12 months, and similar ideas occurring in other cities [15].

Norway

Norway is a country that stands out as a special example of electric vehicles. It is the first country in which every electric car was registered for every 100 passenger cars. The number of these vehicles is the highest per capita in the world, and Oslo is considered head of the city of electric vehicles. Figure 3 shows the number of registered electric vehicles in Norway for period from 2004 to 2018 [16].

Electric vehicles in Norway are considered the cleanest, as even 98% of the electricity used as a plant comes from hydropower. The production and expansion of electric vehicles in this country has influenced the Government to awaken awareness of welfare of electric vehicles through a certain stimulus. This incentive consisted in release of electric vehicles from all non-refundable charges, including purchase taxes and 25% of VAT during purchase. Local authorities have been given option of deciding whether electric vehicles can be parked free of charge. All of these facilitation and successful policies of Norway have led to accelerated growth of electric vehicles on roads.

China

One of the largest and most populous countries in the world also faced the problem of environmental pollution. China was the world’s largest car and fuel consumer in 2009. They imported large quantities of oil that were consumed in the same amount as well. For all of that, the Chinese government has understood this as a serious invitation to do something in the field of reducing emissions of harmful gases and oil imports. Their plans were aimed at two goals: to reduce CO₂, and to increase the use of electric vehicles. The use and production of electric vehicles first came to life in the major cities of China, where six cities were selected through a single project to implement and subsidize the development of electric vehicles, with a commitment to invest $ 9000 per vehicle. A large number of manufacturers came in and presented their models of electric vehicles and announced their mass production. Plans to build the necessary infrastructure are also made. A concept was developed to build 1700 charging stations and 3 million charging points in 2015 [17]. Sales of electric vehicles in China increased by 53%, according to the data from 2017, and their tendencies are aimed at selling 2 million electric vehicles annually by 2020, as well as to completely prohibit the use of engines with internal combustion [18].

The Chinese authorities saw three important benefits through the expansion and promotion of electric vehicles:

1. Economic Opportunities
2. Energy security
3. Pure air [19].

4. Conclusion

Although the views regarding application of electric vehicles are different and very often in complete mutual opposition, increasingly massive use of electric vehicles in the future is realistic. The development of infrastructure and the use of alternative fuel vehicles has seen significant growth in recent years. Technological innovations invested in significant investments and pilot projects carried out within individual countries contribute to accomplishment that the European Commission has set as a goal - complete abolition of conventional vehicles by 2050. Many cities encouraged by EU policies have implemented a number of measures that have resulted in a reduction in dependence on conventional fuel. Since the development and application of renewable energy is becoming more and more current, it is necessary to use this fact and work on co-ordination and creation of common benefits in these areas at all national, European and world levels. It is necessary to create such conditions in which despite the many shortcomings prevailing advantages of using electric vehicles. Disadvantages are time-consuming, studied, and strive to minimize them.

THEORY OF FACTOR EXPERIMENT (MATRIX OF IMPACT) OF GREENHOUSE AS A COMPOSITION SYSTEM FOR BIOGAS PRODUCTION AND REGULATION FOR PERMISSIBLE EMISSIONS OF HARMFUL MATERIALS IN ATMOSPHERE

M.Sc. Veljanovski D., Prof. Jovanovska V. PhD., Jovanovska D., Prof. Hristovska E. PhD.
Faculty of Biotechnical Sciences – University St. Clement Ohridski – Bitola, the Republic of North Macedonia
darkoveljanovski@yahoo.com

Abstract: By applying a complex, exact and scientific approach, was performed the development, calculation and analysis of a complex pilot installation (bioenergetics system consisting of the following elements: greenhouse for early vegetation crops, digester and internal combustion engine powered by biogas). Using the factorial experiment, i.e. applying the matrix of influence, a complete optimization of the internal combustion engine was performed in function of the other elements of the installation. An analysis is also made from the aspect of the positive current EU regulations in the field of air pollution.

Keywords: greenhouse, digester, factor experiment, emissions, EU regulations.

1. Introduction

An intricate situation is elaborated, calculated and analyzed (bioenergetics system consisting of a plastic garden for early garden crops, a digester and an internal combustion engine). Here we are talking about an environmentally friendly energy production system, especially in terms of global warming, because it is with zero carbon dioxide ejection in the atmosphere.

In the installation the producer of biogas is the digester in which is performed continuous delivery of plant biomass from the greenhouse, which ensures continuous production of biogas. This gas is used by a motor generator that produces electricity to illuminate the greenhouse, the needs of the system or the agricultural economy. The waste heat energy from the engine's cooling system is used to heat the greenhouse. The exhaust gases of the engine are sprayed with clean and non-combustible hydrocarbons and are directly used into the plastic garden. They partly carry out the heating of the air and partly supplemental CO₂ yield, which increases the yield of products and biomass in the greenhouse. After the completion of the production process in the digest, there remains a high quality biological material that is used in the greenhouse for the increase on the yield of products and biomass in the greenhouse. As a result of the work of the elements, especially those that can be applied indirectly.

With this theory of factor experiment presented, described and planned in pictures number 1 and number 2, factors of action of the three main elements in the installation are taken into account on the resultant parameters.

To use this theory is necessary:
1. The correct selection of input-output factors for the certain element;
2. Determining the magnitude of impact to a certain factor;
3. Ability to determine the optimal variant of a given element
4. The logical connection of the work of the elements, especially those that can be applied indirectly.

In the given case, although the most distinguished elements are the digester and the greenhouse, the greatest difficulty in completing the matrix of influence is on the internal combustion engine. The reason for this is the need to comment on parameters that are influential or influenced, but not each of them can be measured or visually determined. The point should be taken into account that the internal combustion engine is a machine in which numerous microprocesses take place. Therefore, a great deal of knowledge and scientific concealment of the researcher in the use of this theory is required in order to determine the most optimal variant of the system.

The Directive (2008/50 / EC) for the quality of ambient air and cleaner air for Europe, covers most of the existing legislation (except for the fourth minor directive) without changing the existing air quality targets set out in the old framework air quality directive 96/62 / EC and the three minor directives. This Directive sets new air quality targets for PM2.5 (fine particles), while the four minor directives (the first / 3 / EC) and the second (2000/69 / EC), the third / 3 / EC) and the fourth (2004/107 / EC), give limit values for specific substances in ambient air. Decision of the Council (97/101 / EC) for the exchange of information and data from networks and individual measurement stations of ambient air pollution within Member States.

Commission Decision:

- Commission Decision (2004/461 / EC), which sets out the form and content of the Member States’ annual report on the quality of ambient air in their territories to the Council;
- Directive 2008/1 / EC on Integrated Pollution Prevention and Control;
- Directive 2001/80 / EC on the limitation of emissions of certain pollutants into the air from large combustion installations
- Directive 2001/81 / EC on national upper limits for emissions of certain pollutants;
- Directive 1999/13 / EC on the limitation of emissions of volatile organic compounds resulting from the use of organic solvents in certain activities and installations; (Section 3 - Handbook on the Implementation of EC Environmental Legislation; Air quality – existing legislation.)

4. Conclusion

In such a complex installation, its optimal operation is the function of the optimal operation of each individual element. The discontinuance of optimum work has only in the discontinuous operation of one of the elements and its influence in the direction of the subsequent element, but not in the reverse direction.

The type of material that digests most directly affects the yield of biogas and the time of storage in the digester. Applied plant biomass from early breeding production is a good choice for that spa in the group of organic matter that is most frequently digested in the technical practice. The reason for this is the high numerical value this is obtained in the analyzing of the range of biogas yields obtained from it. Namely, the minimum yield on biogas ranges from 0.42-0.45 (m3 / kgOSM), and the maximum yield on biogas is 0.52-0.55 (m3 / kgOSM). Therefore, the average yield values for biogas for this type of plant biomass are in the group of the maximum and amount to 0, 50 – 0.575 (m3 / kgOSM). In the observed optimal conditions, the relation between the amount of digested material and the daily inflow of biogas is fairly proportional.

Annotation. The purpose of this study is to determine the importance of influencing the effectiveness of social development management of airlines in Ukraine on the economic indicators of their economic activity. The study was conducted on the example of 10 Ukrainian airlines, whose financial statements are officially available during the analysed period of 2007-2017. The results of applying the statistical analysis method showed that spending on social activities, as an indicator of social development is the largest by volume and the best in the positive dynamics of the market leader, the UIA airline. However, the use of the method of analytical alignment to analyze the impact of spending on social activities of the analyzed Ukrainian airlines on the profitability of their sales showed that the strongest impact of the results of social development management on the efficiency of economic activity are in such airlines as Constanta, Artem-Avia, Kharkiv Airlines and Dniprovavia. Consequently, the main hypothesis of the study on the average importance of the impact of spending on social activities as an indicator of the effectiveness of social development management on the economic performance of airlines in Ukraine was confirmed.

KEYWORDS: AIRLINE, MANAGEMENT, SOCIAL DEVELOPMENT, PROFITABILITY OF SALES, SPENDING ON SOCIAL ACTIVITIES.

1. Introduction

The research of problems and prospects of the development of the air transport market in Ukraine was carried out by the authors in the previous publication (G. Zhavoronkova, V. Zhavoronkov, M. Volvach, 2018). However, the social security of this development has not received adequate attention. Indeed, modern trends in world development require airlines to be socially responsible actors of societies in which they operate, and to use trends in world development require airlines to be socially responsible actors of societies in which they operate, and to use trends in world development require airlines to be socially responsible actors of societies in which they operate, and to use trends in world development require airlines to be socially responsible actors of societies in which they operate, and to use

In our view, the practical management of Ukrainian airlines underestimates the priority of social goals and often has a stereotypical view of social issues as an object of exclusive management of state bodies. However, today the harmonization of social and economic goals is very important for the strategic management of human capital of airlines in Ukraine, since the components of the social-commercialization activity of the reflexive-knowledge paradigm have the greatest impact on their socio-economic development (Shkoda, 2018). Applied aspects of managing the social development of airlines in Ukraine need further research.

The purpose of this research is to determine the importance of influencing the effectiveness of social development management of airlines in Ukraine on the economic indicators of their economic activity.

The main hypothesis of the research is that the importance of influencing the spending on social activities as an indicator of the effectiveness of social development management on the economic performance of airlines in Ukraine is average.

2. Literature review

In their study, T. Nadtoka and G. Kakunina (2011) note that the key feature of the social development of the enterprise is a certain type of change, which leads to a qualitatively new state of all social processes and relations in the enterprise. N. Sychova (2015) interprets the social development of the enterprise as progressive quantitative, qualitative and structural organizational changes aimed at improving the social environment of the enterprise and the sphere of social relations with the groups of those interested in the activity of the enterprise such as owners, personnel, consumers, public, business partners on principles of social partnership and participatory approach in management. This author also links social development with changes, and takes into account the impact of the social environment and relationships with stakeholders.

In our opinion, the social environment in Ukraine does not contribute to the rapid social development of domestic airlines. Unpopular social reforms, absence of Social Code, unconsciousness of the priority of social goals solution by airlines delay practical and theoretical understanding of social development. For the transformation of the modern situation, changes are needed both in applied and in the theoretical way. Ensuring appropriate changes requires the development of a methodology for creating a favourable internal and external social environment.

Social development covers a wide range of aspects that are factors of the close social environment of the organization (Shkoda, 2012): organization potential, social infrastructure, working conditions, occupational safety, leisure, material remuneration, socio-psychological climate, social security. All these factors have a full effect on the social development of airlines. For example, according to O. Novikova and L. Logachova (2018), the reform of the Ukrainian labour protection management system in Ukrainian enterprises needs to improve the scientific and methodological support for the analysis and evaluation of industrial safety and occupational risk, the modernization of the system of benefits and compensations under labour conditions on the basis of a risk-oriented approach.

Thus, the social development of the airline can be characterized as noticeable changes in the air transport company, determined by the transition of all social relations and processes to a qualitatively new state under the influence of factors of the internal
and external environment. The social development of the airline's employees as human capital carriers is a consequence of both the targeted activity of the people who are the subjects of this process and the indirect effect of production on the social groups of the enterprise, the population of the region, and the consumers of the air transport company's services.

According to N. Sychova (2015), the social development management of the enterprise is a process of improving the internal social environment and conditions for the implementation of labour activities of the personnel, which allows enterprises to achieve high results of economic activity. Agreeing in general with this viewpoint, we consider it useful to add that in order to successfully manage the social development of the airline it is necessary to identify clearly the real goals of social development, the ways of achieving which must be prescribed in the social policy of the air transport enterprise and provided with the necessary resources. Of course, the implementation of the developed social measures is essential.

According to the authors’ point of view, the social policy of the airlines represents the goals and measures related to the provision of additional social benefits, services and benefits to workers, which ensure the involvement of airline employees. At most, enterprises, along with mandatory social programs, a large number of voluntary programs are being implemented. Implementation of compulsory and voluntary social programs is the implementation of the social function of the airline, which, in our opinion, should be considered in conjunction with the social policy of the state, since the activities of the enterprise in the social sphere are determined by social policy and oriented on, it general laws and contributes to the achievement of the main goals. In view of this, the authors believe that the social policy of the enterprise and the social policy of the state are influenced by the trends of world development, which, in our opinion, should be supplemented with the main components and presented in Table 1.

Source: compiled by the authors on the basis of (A. Kolo, 2008; O. Mart yakova, V. Zubenko, 2011)

Indeed, it is evident that the economic realities and social development of the country, and therefore the enterprises, correlate with each other, the transformation of social and labour relations and social expectations of airline employees and the airlines themselves as employers is taking place.

At the large enterprise, social development management is implemented by the social unit of the personnel management department, while in the medium or small enterprise, the specified functions are performed by individual employees of the personnel management department or employer. The tasks and functions of these employees have their own specifics. In the process of carrying out work on social development of personnel, they must, by means of justified provision of additional payments and benefits, encourage the employees to their further development.

3. Research methodology

The research of determining the importance of influencing the effectiveness of management of the social development of airlines in Ukraine on the economic indicators of their economic activity was conducted on the basis of available official data of the Stock Market infrastructure development agency of Ukraine (SMIDA, 2019) for 2007-2017 for 10 airlines in Ukraine.

In the process of the research, statistical methods were used to analyse the dynamics of spending on social activities in Ukrainian airlines as a significant indicator of social development.

To analyse the impact of spending on social activities of Ukrainian airlines on the profitability of sales, the method of analytical alignment was applied by the authors. The trend model is considered to be adequate to the process being studied and reflects the tendency of its development in time, when the provided values of $R^2$ are close to 1.

An important problem that was solved with the application of the method of analytical alignment was the selection of a mathematical function for which the theoretical levels of a row are calculated. The trend model, in which the determination coefficient had the highest value, became the most adequate for each estimated dependence.

Also, the correlation coefficient was determined, which made it possible to measure the statistical dependence (the level of influence of the argument $x$ (spending on social activities of Ukrainian airlines) on the function $y$ (profitability of sales)). It is taken into account that the correlation coefficient can range from -1 to +1. Therefore, based on the value of the calculated coefficient of correlation on the Chaddock scale, the conclusion was reached on the presence or absence of stochastic dependence: 1) from 0 till ±0,3 – absent; 2) from ±0,3 till ±0,5 – weak; 3) from ±0,5 till ±0,7 – moderate (average); 4) from ±0,7 till ±1 – strong.

4. Research results

The success of measures to improve the social development of airlines was analysed by assessing their spending on social activities and analysing their impact on profitability of sales of Ukrainian airlines for the period 2007-2017.

The results of the analysis of the dynamics of spending on social activities for Ukrainian airlines are shown in Figure 1. It was also used in the calculations the projected spending on social activities of airlines in Ukraine for 2018-2019, as the official statistical reporting for 2018 at the time of the research was not available.

On the basis of the analysis of the obtained results (Fig. 1), it is noted that in the social development of air transport enterprises, several trends are outlined:

1. growth of rates of increase of spending on social activities of the leader of the air transportation market, Ukrainian International Airlines (UIA);
2. slight increase for airlines URGA and Ukrainian Helicopters; a certain deceleration in the rate of increase of spending on social activities for airlines Bukovina, Dniprovavia;
3. saving at the same level for airlines Artem-Avia, Kharkiv Airlines, Constanta, Spets-Avia, and Ukraine-Aeroalliance.

The increase in spending on social activities enables the airline UIA to increase the flexibility of social programs, to strengthen the individual approach, to enrich the content of social programs, due to the need to meet new social needs and problems. All this confirms that the social function of this airline is developing and strengthening, which contributes to the development of its personnel, the formation of partnerships and increased efficiency of work.
The results of analytical alignment for spending on social activities of airlines are presented in Table 2. As a mathematical model of the trend for all Ukrainian airlines analysed, the second-order polynomial is chosen, since the determination coefficient $R^2$ has the highest value among the proposed by the program Microsoft Excel.

Most of the existing polynomial dependencies indicate the relative stability of the impact of the dynamics of costs on the social measures of Ukrainian airlines on the profitability of sales with a steady slight slowing down of their growth rates, as evidenced by the small negative value of the coefficients $a_2$ (Table 2).

For the airlines of Bukovina, UIA, Spets-Avia, Ukraine-Aeroalliance, Ukrainian Helicopters and URGA, no significant stochastic dependence of the profitability of sales ($y$) on the factor characteristic of deductions on social measures ($x$) was found during the relevant period.

The calculated correlation coefficient $R$ (Table 2) indicates the strong stochastic dependence of the profitability of sales of the airline Constanta on the factor indicator of spending on social activities for the relevant period. This means that in this airline, social development has a significant impact on the economic performance. Also, the influence of the factor character $x$ on the resulting indicator $y$ should be taken into account in the social development management of the analysed airline.

The moderate (average) value of the correlation coefficient $R$ occurs in the airlines Artem-Avia, Kharkiv Airlines and Dniproavia. This also points to the very significant dependence of the profitability of sales on the spending on social activities of these airlines.

For the airlines of Bukovina, UIA, Spets-Avia, Ukraine-Aeroalliance, Ukrainian Helicopters and URGA, no significant stochastic dependence of the profitability of sales ($y$) on the factor character $x$ was found during the relevant period.

The evaluation of the constructed regressive economic and mathematical models based on Student’s $t$-criterion (Table 2) confirms their adequacy under the following conditions (to define critical values the appropriate statistical tables were used (Vitlinsky, 2008)):

$$\text{Constanta} - t_{\text{critic. value}} (\sigma/2; k) = 2.306$$
$$t_{\text{critic. value}} (\sigma/2; k) = t_{-t_{\text{critic. value}} (\sigma/2; k)} = -2.306$$
Artem-Avia, Kharkiv Airlines and Dniproavia – $t'_{\text{critic.value}}$ ($\alpha/2; k$) = 1,397 at the level of significance $\alpha = 0.2$ and degrees of freedom $k = n - m - 1 = 8$, moreover $t_{\text{critic.value}}$ ($\alpha/2; k$) = $-t'_{\text{critic.value}}$ ($\alpha/2; k$) = -1,397;

Bukovina – $t'_{\text{critic.value}}$ ($\alpha/2; k$) = 1,108 at the level of significance $\alpha = 0.3$ and degrees of freedom $k = n - m - 1 = 8$, moreover $t_{\text{critic.value}}$ ($\alpha/2; k$) = $-t'_{\text{critic.value}}$ ($\alpha/2; k$) = -1,108;

URGA – $t'_{\text{critic.value}}$ ($\alpha/2; k$) = 0,889 at the level of significance $\alpha = 0.4$ and degrees of freedom $k = n - m - 1 = 8$, moreover $t_{\text{critic.value}}$ ($\alpha/2; k$) = $-t'_{\text{critic.value}}$ ($\alpha/2; k$) = -0,889;

UIA, Spets-Avia, Ukraine-Aeroalliance – $t'_{\text{critic.value}}$ ($\alpha/2; k$) = 0,706 at the level of significance $\alpha = 0.5$ and degrees of freedom $k = n - m - 1 = 8$, moreover $t_{\text{critic.value}}$ ($\alpha/2; k$) = $-t'_{\text{critic.value}}$ ($\alpha/2; k$) = -0,706;

Ukrainian Helicopters – $t'_{\text{critic.value}}$ ($\alpha/2; k$) = 0,546 at the level of significance $\alpha = 0.6$ and degrees of freedom $k = n - m - 1 = 8$, moreover $t_{\text{critic.value}}$ ($\alpha/2; k$) = $-t'_{\text{critic.value}}$ ($\alpha/2; k$) = -0,546.

These obtained results also confirm the main hypothesis of this research as the regressive economic and mathematical models with strong and average values of the correlation coefficient have the confirms their adequacy under the highest level of significance.

5. Conclusions

The results of applying the statistical analysis method showed that spending on social activities as an indicator of social development is the largest by volume and the best in the positive development is the largest by volume and the best in the positive and degrees of freedom $k = n - m - 1 = 8$.

It is significant that the majority of airlines, whose spending on social activities were stable during the analyzed period of 2007-2017, also have the strong (airline Constanta, Artem-Avia, Kharkiv Airlines and Dniproavia. Consequently, the main hypothesis of the research was confirmed on the average importance of influencing the spending on social activities as an indicator of the effectiveness of social development management on the economic performance of airlines in Ukraine.

Airlines Artem-Avia, Kharkiv Airlines and Dniproavia are the largest by volume and the best in the positive spending on social activities as an indicator of social activity are in the airlines Constanta, Artem-Avia, Kharkiv Airlines and Dniproavia. Consequently, the main hypothesis of the research was confirmed on the average importance of influencing the spending on social activities as an indicator of the effectiveness of social development management on the economic performance of airlines in Ukraine.

Abstract: The statistics demonstrate that giving the qualified first aid at the scene before admission is significantly less frequent than would be expected.

Medical care at the pre-hospital stage is of particular importance in cases of manifest circulatory and respiration disturbances, clinical death, bleeding, fractures, when a failure or delay to render assistance quickly leads to a significant deterioration of the body condition and even death.

The majority of the victims die at the pre-hospital stage, resulting in high importance of qualified first aid in the first moments after injury.

KEY WORDS: ROAD TRAFFIC INJURIES, URGENT CONDITIONS, RESUSCITATION.

1. Introduction

The intensive development of transport communications has exacerbated the problem of conflict with human flows in modern society. Vehicles are distinguished by high power and speed. The dynamics that accompany this development had naturally led to a significant increase in trauma in people, the cause of which is a conflict with the traffic flows. In recent years, among the causes of mortality of people aged 5 to 45, road accidents ranked second [1].

In modern conditions, road accidents are characterized predominantly by pelvic fractures, in combination with head segments injuries and other bodily injuries. Soft-tissue damage and ligamentous apparatus injury are often overlooked; attention often is not paid to hidden injuries. In addition, the statistics demonstrate that giving the qualified first aid at the scene before admission is significantly less frequently than would be expected. For example, first-aid assistance is provided by employees of the road patrol service only in 1% of cases; assistance from the fellow travelers or from drivers and travelers of other vehicles is provided in 10% of cases. The reason for this is primarily a low level of skills of first medical aid to people found at the accident site.

Numerous researches and tests have revealed that at a frontal collision of the adapted bus, the angular speed and acceleration of head of a traveler with restricted mobility, which is much larger than of a common traveler, causes closed trauma, while at a “collision from behind”, cervical vertebrae are mostly damaged. Therefore, during such road accident, it is necessary to take into account the specificity of the mentioned injuries, as well as the administration of first aid.

In the evacuation process from the accident site, the rapid administration of first aid is of particular importance. In cases of manifest circulatory and respiration disturbances, clinical death, bleeding, open and closed fractures, thermal and chemical burns, delay to render assistance quickly leads to a significant deterioration of the body condition and even death.

Statistics confirm that the mortality rate in road accidents is as follows: 50% of victims die in the first seconds and minutes of accident, 30% of them lose their lives during the first two hours after the injury, and 20% of victims - 5 days after. From this data, it clearly appears that many victims of road accidents lose their lives at the pre-hospital stage. More than half of them die at the accident site before the arrival of a medical emergency team, which emphasizes the importance of medical assistance from the first moment after the injury.

According to the official statistics, more than 40 000 road accidents occurred in Georgia in 2018. More than half of those who lost their lives in road accidents are people of active working age from 22 to 40. More than 20% of the injured are maimed. 9047 people were injured in road accidents occurred in 2018, and 459 people lost their lives. Of these, 13 were children under the age of 7. According to the 2018 statistics, the number of road accidents increased by 6% compared to the previous year, followed by the increase in the number of the injured people.

The reasons for accidents with fatal consequences are as follows:
- 27% - of the rules for maneuvering;
- 26% - speeding;
- 19% - swerving into oncoming traffic;
- 9% - driving under the influence of alcohol;
- 19% - different violations.

The mortality rate among children in road accidents is 4-6 times higher in comparison with the Nordic and economically developed countries of Western Europe. According to expert estimates, a significant number of victims lose their lives because of incomplete and delayed medical care, although injuries sustained in road accident were not fatal [2]. Lethality of injuries sustained in road accidents largely depends on the level of preparation of specialists of an ambulance team, their skills to persons under life-threatening conditions, as well as on the proper organization of life-saving and anesthesiological treatment at the scene and in the evacuation process [3].

Experience gained in clinical practice in the world has clearly demonstrated the important parts of these problems that have not yet been resolved so far: belated diagnosis, imperfect assessment of the severity of injuries sustained in road accidents, high frequency of complications, high rates of injuries, the predominance of injuries among people of working age. Most of the severe consequences can be explained by belated and inadequate diagnosis. Experience has shown that in the case of polytrauma, the medical staff cannot reveal injuries in a timely manner, which leads to the post-complication development and prolonging the treatment duration, and often to patient's disability or fatal outcome. During polytrauma, there is a variety of the injuries localization and severities, as well as a multitude of their possible combinations for the victims.

The complications of polytrauma diagnosis caused in road accidents are caused by their pathogenesis, which often leads us to typical symptoms that ultimately translate into to diagnostic pitfalls. This is due to the fact that polytrauma sustained in road accident is characterized by a number of peculiarities: there is exhibited a syndrome of mutual complication of factors affecting the process; often the process preceded by the less severe symptoms, but with more pronounced pains. At this time, they eliminate the symptoms of the main damages, which call an urgent operational intervention. Many experts believe that there are distinctive features of polytrauma:
- Syndrome of mutual aggravation;
- Atypical symptoms that complicate diagnosis;
- High likelihood of the development of traumatic shock and massive loss of blood.
- Instability of the compensation mechanisms, and a large number of complications and fatalities.

Characteristic features of the assistance to the victims of road accidents are represented by the reconciliation of the diagnostic process and the immediate elimination of significant injuries. Among them, the priority is given to the emergence evacuation victims to hospital; the measures slowing the evacuation process are undertaken only in accordance with vital indications. In addition, it is necessary to strictly adhere the algorithm for action, which can lead to serious diagnostic errors. First of all, this is the assessment of the life-threatening disorders of the victim's respiratory and circulatory systems.

Decision on the time of transportation of victim is made in accordance with the life-threatening disorders, which is required for transferring patient the clinic. In case of the need for undertaking medical reanimation measures, transportation can only be possible after overcoming life-threatening situation [5].

2. Preconditions and means for resolving the problem

Primary medical examination (not more than three minutes):
1. Signs of respiratory distress: strongly-marked cyanosis, futile attempt to breath in, chaotic arrhythmic breathing, inclusion of auxiliary respiratory muscles.
2. Primary cause – full or partial obstruction of respiratory tract. In an examination, it is necessary to exclude severe breast damage through auscultation: open or pressure pneumothorax, hemothorax, breast damages.
3. Hemodynamic assessment: it is necessary to measure heart rate and blood pressure. The clinically significant tachycardia that requires therapeutic intervention, among under 1 year old children, is 220 bpm, among older children - more than 200 bpm, bradycardia among under 1 year old children - less than 60 bpm, among older children - less than 50 bpm.
4. Systolic pressure for children aged 1 year up can be calculated according to the formula: 90+ (2 X age in years). Hypotension among under 1 year old children is considered to be a reduction in systolic pressure up to 70 Mmhg, and among children aged 1 to 10 -70 + (2 in X age in years), for children aged 10 year up - less than 90. The pulse can be checked on a radial artery, if the blood pressure is greater than 80 Mmhg, on a femoral artery -> 70 Mmhg, on a carotid artery -> 60 Mmhg. For babies, it is recommended to check the pulse on a brachial artery, and for older children - on a carotid artery [3].

Bradycardia itself does not provide adequate perfusion, so the treatment of deep bradycardia should be carried out in the same way that treats asystolia.

1. Cardiopulmonary resuscitation

During the primary medical examination of the victims of road accidents, special attention is paid to the signs of clinical death and/or circulatory deficiency: pulselessness on the major veins, the absence of spontaneous breathing, status of pupils, the absence of heartbeats, considerable bradycardia (heart rate below 60 among under 1-year-old children, and below 50 bpm, among older children, in case of the presence of circulatory failures). The first stage of cardiopulmonary resuscitation involves:
- unblocking airways;
- breathing management and lung ventilation;
- preservation of blood circulation and stopping bleeding.

These factors in the process of cardiopulmonary resuscitation are often denoted by the ABC abbreviation.

1.1. Airway breathing

In order to ensure airway breathing, it is necessary to open the victim's mouth. If clotted blood or foreign body were lodged in the victim's esophagus, it is necessary to clean up by means of the aspirator or napkin. If obstruction is caused by tongue, it is necessary to put the lower jaw forward. If the patient is unconscious, then it is possible to install the S-type air duct in his/her body. The dimension of this air duct should be adapted to the patient’s age. The triangular method of covering (pushing back the head, opening the mouth and putting the the lower jaw forward) is considered to be the best method of post-traumatic recovery of airway breathing [6] However, if there the reason to believe that the backbone neck section is injured, then the victim’s head should be pushed back not too far. In such a case, the head is pushed back moderately (by stabilizing the neck section).

2. Pharmacological therapy

1. If there were signs of cardiac deficiency, the drug to be chosen is an adrenaline (epinephrine). It is injected intravenously or into the bone. The dosages are shown in Table 1 [3].

<table>
<thead>
<tr>
<th>Patient’s weight, kg</th>
<th>An initial dose for intravenous and intra-bone injection</th>
<th>The second and further injection doses</th>
</tr>
</thead>
<tbody>
<tr>
<td>10</td>
<td>0,1 mg, 0,1 ml (1:1000)</td>
<td>1–2 mg, 1–2 ml (1:1000)</td>
</tr>
<tr>
<td>20</td>
<td>0,2 mg, 0,2 ml (1:1000)</td>
<td>2–4 mg, 2–4 ml (1:1000)</td>
</tr>
<tr>
<td>30</td>
<td>0,3 mg, 0,3 ml (1:1000)</td>
<td>3–6 mg, 3–6 ml (1:1000)</td>
</tr>
<tr>
<td>Adults</td>
<td>1,0 mg (standard dose)</td>
<td>Variation is provided</td>
</tr>
</tbody>
</table>

It should be noted that in the resuscitation process, adrenaline can be administered in every 3 minutes before the heart rate is recovered.

After injecting any drug into the peripheral vein or bone, it is necessary to immediately introduce 5-10 ml of isotonic solution, in order to accelerate inclusion of drug into the central circulation [7].

If it is not possible to enter the venous or intrabone channel, and there is a need for injecting the drug externally, there is used the intratracheal method of drug instillation: into the endotracheal tube (if intubation was performed). At this time, the drug is doubled and dissolved in 1-2 ml of physiological solution. The total volume of one-time injected drugs can reach from 20 to 30 ml. Adrenaline intake in the heart is used only when it is impossible to treat by other methods.

2. In case of urgent need, prior to intravenous injection, we can apply the method of sublingual injection of drug (into the muscles of mouth cavity), which allows for urgent intravenous injecting of the required drug dose, since there is no time for venous puncture.

In this case, there is used the Three Deuces rule: the drug is injected 2 cm from the front of chin, by means of the intramuscular injection needle at a depth of 2 cm in sublingual muscles in the direction towards the crown, the total volume of which does not exceed 2 ml (1 ml for children of up to age three). The drug dose should be standard, without dilution.

The effectiveness of heart function for kids is mostly by frequency of the pulse, so during bradycardia, it is treated as in the case of asystolia. Along with adrenaline, there may also be selected the atropine. It is administered by intravenous, intraosseous or endotracheal injection at a dosage of 0,02 mg/kg, approximately 0,1 ml per year of child’s age, but no more than 0,6 milliliters. In endotracheal injection, this dose is doubled. In case of a low effectiveness, the repeat dose can be given to patient in 3 to 5 minutes. In the cases of prominent ventricular tachycardia or fibrillation, the drug to be selected is lidocaine on 1-2 mg/kg (intravenous, intraosseous or endotracheal) in every 3-5 minutes up to the total dose (on 3 mg/kg).

3. Infusion therapy

Severe trauma is always accompanied by a shock complication, so at the pre-hospital stage, it is necessary to provide intravenous or intrabone injection of liquid. For this purpose, there is mostly used by the Ringer’s balanced salt solution. At the initial stage, it is injected at a dose of 20 ml/kg. Infusion is also done at the rate of normal blood pressure.

The second bolus of infusion is repeated with the same dose, and if the first bolus does not improve signs of tissue
for intraperitoneal hemorrhage, it is expedient to initiate infusion with colloidal solutions, among which the most recommended in the pediatrics is hydroxyethylated starch 130/0.4, which can be injected at a dose of 20 ml/kg. It has minimal side effects [3].

The next stage is a crystalloid infusion. There has been confirmed the prospect for the use of method of a low-volume infusion of the hypertonic solutions of sodium chloride at the victim evacuation stage. Also, there have been registered the drug of a mixed composition – Hyperhaese, which includes hydroxyethylated starch 2000/0.5 and a sodium chloride 7.2%-solution. The maximum volume of its injection dose is 4 ml/kg. The anesthesiologist-reanimatologists of the pediatric field have justified a high effectiveness of using Hyperhaese at the evacuation stage, when providing the first aid to children injured in road accident.

4. Analgo-sedation

Specific requirements are applied to analgetic and sedative methods and agents for the victims of road accidents. They should be distinguished by the technical simplicity, high effectiveness, fast pain medication, they should not have a depressing effect on the life-saving systems. Of these drugs, an ambulance team must have a

- narcotic analgetics – morphine or promedol - are allowed for newborns with a dose of 0.1 - 0.5 mg/kg/min. In this case, 1 ml of a 0.1%-adrenaline solution is dissolved in 200 ml of physiological solution, and titration is carried out in the same way as with dopamine.

- morphine or promedol - are allowed for newborns with a dose of 0.1 - 0.5 mg/kg/min. For this, 0,5 ml of a 4%-dopamine solution is dissolved in 200 ml of physiological solution, and titration is carried out in the same way as with dopamine.

5. Medical care in the process of evacuation of victims

- to undertake all preparatory and preliminary measures required for transportation (preparation of victim and vehicle, providing opportunities for injections, sanitation of the mouth cavity, esophagus and trachea, as well as conducting oxygenotherapy and so on);

- to maintain all conditions for proper transportation for a particular victim, in accordance with the severity level of his/her state, taking into account the major pathological syndromes (monitoring of vital functions of body, conducting the infusion therapy, readiness for cardiopulmonary resuscitation, providing artificial lung ventilation and so on);

- to pay special attention to the persons with restricted mobility in the adapted bus, since in road accident, they are mostly injured in the head and neck areas, which is not visible during the visual inspection. Therefore, their above mentioned organs must be fixed, so that their state won’t become even more severe in the transportation process.

- to determine the complex of those treatment measures that are necessary in the transportation process of the victims (infusion therapy, artificial lung ventilation, the use of medicines for the preservation of vital functions, and so on).

Prior to the start of transportation, the victims will be provided with additional rapid physical examination of:

1. Head - skull bones and tissues, facial skeleton, eye damage, hemorrhages, liquorhrea;
2. Neck – subcutaneous emphysema, trachea and backbone neck section damage;
3. Breast bones – respiratory excursion, asymmetry, breast skeleton damage;
4. Abdomen – we need to remember that in case of injury caused by a sharp object, there are often damaged liver and kidney, which leads to intra-abdominal hemorrhage;
5. Extremities – to assess the voluntary movements;
6. Skin – damage detection;
7. Additional neurological examination.

When starting the transfer of victim and during the transportation process, it is necessary to maintain systolic blood pressure at 90 Mmgh (80 Mmgh for children of up to age three), and the pulse rate should be within the 10%-deviation limits, according to ages. Arterial hypertension should be eliminated as soon as possible. In the case of hypertension maintenance and intravenous or intra-bone active infusion therapy in the form of constant infusion, there are used injection of dopamine with an average dose of 6-8 mkg/kg/min. For this, 0.5 ml of a 4%-dopamine solution is consumed in 200 ml of physiological solution, and there is carried out drip titration under blood pressure control. If there is no dopamine, there is used adrenaline with a dose of 0,1 - 0,5 mg/kg/min. In this case, 1 ml of a 0,1%-adrenaline solution is dissolved in 200 ml of physiological solution, and titration is carried out in the same way as with dopamine.

3. Conclusion

A large number of complications and fatal consequences are associated with the belated delivery of the victims of road accidents to the hospital (the “golden hour” rule), insufficient fixation of fractures, belated diagnosis and operative treatment of all injuries, inconsistencies between the adequate rehabilitation and out-of-hospital care.

The inevitability of road traffic injury conditions the need for developing the uniform tactics of providing assistance to the victims. Under great pressure of time, one of the methods for excluding diagnostic and medicinal errors for the victims injured in road accidents is a reasonable use of the algorithm and treatment schemes for providing medical care. The right treatment-diagnostic tactics by an ambulance team, timely hospitalization of victims with providing the medical care at the accident site and during the transportation process, as well as continuous retraining of medical personnel for improving their practical skills, pertain to the reserves in combating the grave consequences of road accidents.

The use of the correct algorithm for providing medical care to the victims of road accidents, dynamic observation and continuity in the stages of treatment contribute to improving the health quality by general and individual criteria (physical strength, positive emotions, activity, workability, and fulfilling life in a social environment).

Abstract: Based on the status of the maritime country of Georgia, we studied the increasing risks of the pollution by the ballast water and wastewater volume increase in the sea caused by the volume of freight turnover of Poti and Kulevi sea ports. For this, we conducted research in two directions: on the theoretical and laboratory studies we have identified the risks of contamination of ports and waste water pollution.

First of all, on ships arriving in ports, we took as ballast and wastewater samples and analyzed in accordance with the legislation:

1. Ballast water analysis from tanker "Metin K" from Kulevi, shows that increased nitrogen +6 mg /l, oilseeds +0.7 mg /l, nitrates 1.35 mg /l and nitrites-0.35 mg /l

2. Poti Port - N 5 Ventilation Examples of Weight Watchers Examples of Weighted Particles 4.0 mg /l, Ammonium 1.67 mg /l of ballast water analysis shows that the total amount of oil nitrogen is 0.6 mg /l, + 0.7 mg /l, nitrates 1.3 mg /ld nitrites - 0.35 mg /l

As a result of these two studies, based on reliability and risk theory of Kulevi, the mean value of salinity (TDS) is equal to: 10.85, for Poti port, the mean value of salinity (TDS) is equal to 12.34.

In the theoretical and laboratory studies we have identified the risks of contamination of ports and waste water pollution.

KEYWORDS: WASTEWATER, BALLAST WATER, RELIABILITY, RISK.

1. Introduction

The transport infrastructure of Georgia is unimaginable without the development of marine ports, especially for the sea ports of Batumi, Poti and Kulevi. They have a crucial role in shipping of marine cargoes. The development of ports should be proportionate to other transport infrastructure of Georgia. Therefore it is necessary to develop a scientifically justified program for the development of Marine Infrastructure of Georgia, which once again indicates the goal of our research to study the risks of polluting the pollution of the Poti and Kulevi sea ports by increasing the volume of cargo turnover.

2. Preconditions and means for resolving the problem

It should be noted that the necessity to provide ecological safety of marine ports under the strategic direction of the country, located on the Black Sea, which is directly related to the scientific study and prediction of the ecological problems of the Black Sea. In addition, as it is known, the ecological environment of the Black Sea depends mainly on the amount of oxygen (%) and bacteria, salinity (TDS), water acidity (pH), air (t1) and sea temperature t2 (CO). Special attention should be paid to the study of the number of oxygen in the vertical layer of the sea (depth 100 m), where the photosynthesis process is active and promotes the viability of the flora and fauna. Taking into consideration all this, the scientific research of the Black Sea ecological issues and its prediction allows us to evaluate the main ecological parameters in the Black Sea, specify their quantitative and qualitative characteristics, new vulnerable areas of the sea coast, which at the next stage will allow us to fully evaluate the Black Sea ecology problems and ecological safety measures of coastal areas and surrounding areas are planned.

In the theoretical study of the thesis the study of the main ecological parameters of the Black Sea are presented. The use of conducted studies in practice will enable us to assess the ecological security of Kulevi and Poti ports and adjacent territories located within the boundaries of Georgia, which is one of the main strategic and economic priorities of Georgia's economic and social development. We conducted surveys in two directions: on the sensitive areas of the Kulevi and Poti pipeline terminals and ships in the port.

The aim of the first research carried out in 2015-2017 was to take samples of water samples in the seaside zones and measuring the main parameters:
1. Fixing the water (t1) and air (t2) temperature;
2. Water acidity (pH);
3. Determination of quantitative indicators of salts (TDS).

First of all, on ships arriving in ports, we took as ballast and wastewater samples and analyzed in accordance with the legislation:

The prediction of sea water acidity (pH) of Poti (sea level) - The surveys carried out in the Black Sea waters of Georgia, whose statistical rank has also been 50 points, allows for a sea water acidity (pH), the mean value of which is:

\[
\frac{\sum_{i=1}^{50} (pH_i)}{50} = 8.37
\]

During the 4 seasons of 2017 for the Kulevi berth. Acidity (pH), the average value of which is equal to:

\[
\frac{\sum_{i=1}^{50} (pH_i)}{50} = 8.34
\]

3. Conclusion

As a result of the tests carried out by reliability and risk theory, the average value of salts (TDS) for the Kulevi berth is equal to: 15.12 mg / dm³ and acidity - 8.34; For Poti Port, the average value of salinity is 15.60 mg / dm³ and acidity - 8.37.

In the theoretical and laboratory studies we have found that the risks of contamination of ports and ballast waters are expected to increase.

“Results of laboratory chemical research on Poti and Kulevi water pollution are given in the following tables (1, 2, 3, 4). Pollution indicators are comparable to international standard standards as well as surface water pollution sanitary norms, with all metallic content not exceeding the permissible concentration concentrations (black, cold, water, cadmium, copper, bullet).

Secondly, the research of the "Poti (landing-stage) Water and Air Relative Temperature Forecast" was carried out during the 4 seasons of 2017. The average value of relative temperature is equal to:

\[
\frac{\sum_{i=1}^{50} (T_{rel})}{50} = 396.25
\]

The average value of relative temperatures during the 4 seasons of 2017 for the Kulev berth is equal to:

\[
\frac{\sum_{i=1}^{50} (T_{rel})}{50} = 21.54
\]

“Water Potential (TDS) Forecast” - One of the most important features of the Black Sea ecological parameters is the determination of salinity of sea water, which basically determines the state of flora and fauna. The statistical order obtained as a result of the survey results in 50 points - the law of distribution of salinity change in the Black Sea by using reliability and risk theory. "The mean value of salinity of Poti berth (TDS) is equal to:

\[
\frac{\sum_{i=1}^{50} (TDS)_i}{50} = 689.13
\]

The average value of salinity (TDS) during the 4 seasons of 2017 at Kulev berth is equal to:

\[
\frac{\sum_{i=1}^{50} (TDS)_i}{50} = 21.54
\]

CO₂ EMISSIONS OF E-MOBILITY

Prof. Lech J. Sitnik DSc. PhD
Faculty of Mechanical Engineering – Wroclaw University of Science and Technology, Poland
lech.sitnik@pwr.edu.pl

Abstract: E-mobility is generally regarded as a zero emission. This sentence can only be true in a very small scope, as only in relation to selected parameters and in a very limited its dimension. An example of this is the measurement of CO₂ emissions from BEV (battery electric vehicle), which is known to be zero. The situation can change radically if it will be take into account the emissions in the production of electricity that is necessary for the movement of this type of vehicles. This paper presents this problem, taking into account the energy mix in various countries of the European Union. Simulation studies show that there are already countries in the EU in which the operation of electric vehicles makes sense. Especially when it concerns CO₂ emissions. Emissions below the standards for 2025 can be obtained there. Unfortunately, in most EU countries, the operation of BEV is associated with an increase (in relation to today) of CO₂ emissions. Without the change of energy policy, and in particular the energy mix, the introduction of e-mobility is problematic.

Keywords: E-MOBILITY, EMISSIONS, CO₂

1. Introduction

E-mobility is treated as emission-free. Generally, this sentence can only be true in a very small range. Namely, about selected parameters and in a very limited using area. An example of this is the measurement of CO₂ emissions in the immediate vicinity of BEV (battery electric vehicle). The situation can change dramatically if you take into account the emissions in the energy production necessary for car traffic. This work presents this issue taking into account the energy mix in the various countries of the European Union.

In Figure 1 is the energy by sources in EU countries given.

![Fig. 1 Energy by sources in some countries in Europe. (CT – conventional thermal, NC – nuclear, HY – hydro, WD – wind, OR- other resources, based on [1])](image)

As can be seen in the European Union there is a strong diversification of sources of electricity. In some countries the dominant role is played by conventional sources, while in others the acquisition of electricity from renewable resources is definitely more important.

But nowhere has such a state of affairs been achieved that all electricity comes from renewable resources.

Today’s electricity production covers today’s needs. E-mobility is “new” in energy demand. Hence the question arises from which energy sources e-mobility will be powered, and in particular how it will affect emissions.

When discussing emissions, the most common issues are global emissions such as CO₂ emissions. However, from the point of view of people, also important are the emissions of PM – solid particles (e.g. from grated tires or roadways), NOₓ – nitrogen oxides, SOₓ – sulfur oxides or HC – hydrocarbons.

Generally, emissions are also divided into so-called low emissions (smog) and high emissions.

Such a division may perhaps make sense, but each emission has a negative impact on people and the environment, and unfortunately there is no exception.

The problem of emission assessment is therefore multifaceted. This work is devoted to the global approach to emission issues by assessing CO₂ emissions during the operation of electric vehicles. It goes without saying that with the emission of CO₂, the emission of the above compounds will follow. These emissions are not linearly correlated. This will have to be subjected to a deeper analysis, for which it is also necessary to develop appropriate methods, and this publication is also devoted this issue to.

The issue of emissions from e-mobility can be considered in static terms (thus analyzing what is happening at a given moment) or in dynamic terms, thus as a function of time (for example including the increase in the number of electric vehicles).

In this work the issue was treated statically. But even in this case there are issues that cannot be omitted.

Such issue is, for example, the issue of energy import and export between countries. In one country, more “pure” energy can be produced and this energy is exported to a country that produces “dirty” energy. Then, in the importing country, “more pure” energy is used. Of course, the opposite is also possible. This undoubtedly affects energy LCA in individual countries.

An important factor affecting energy LCA is also the use of electricity, by BEVs, in individual countries. The issue here is a way of assessing the use of electricity during the natural exploitation of vehicles.

These issues are (somewhat) more accurately presented in this publication.

2. Well-to-Wheels methodology

The methodology presented here as chapter 2, 3 and 4 are on basis of [2] The methodology considered in this article is Well-To-Wheel (WTW) detailed in version 4a of the [3]

This approach allows quantifying the amount of energy required for greenhouse gas emissions resulting from the production, transport and distribution of conventional and alternative fuels for road transport (Well-To-Tank, WTT), as well as for quantifying the performance of various drive units (Tank-To-Wheels, TTW).

Compared to the Comprehensive Attribution Life Cycle Assessment (LCA) approach, WTT considers part of the LCA impact category “energy consumption” and “greenhouse gas emissions”.

In the WTW approach, emissions related to the construction of equipment, maintenance and decommissioning of fuel and vehicle production plants, including material cycles, are not taken into account. Water pollution requirements or emissions are not taken into account if they do not affect GHG emissions. GHG included is carbon dioxide, methane and dinitrogen monoxide. The WTW methodology can be seen as a simplified LCA, designed to assess only energy consumption and greenhouse gas emissions from the use of road transport fuels.

3. CI – Carbon intensity of electricity

Carbon intensity of electricity can be defined as the GHG emitted for producing or using a certain amount of electricity as shown in equation (1):
4. Electricity trade and carbon intensity

The carbon intensity of the electricity consumed in a country depends also on the CI and amount of electricity traded with other countries. Logically, electricity imported in a country embeds also the GHG necessary for its production, so a WTW (or LCA) calculation aiming at realistically representing the carbon intensity of electricity consumed, should also consider the trade aspect, especially for countries having high electricity imports.

For the electricity supplied (EIS) to a national network, considering the trade, is defined by the IEA with equation (2):

\[
EIS = \text{El}_{\text{net production}} - \text{El}_{\text{pumping}} + \text{El}_{\text{Imports}} - \text{El}_{\text{Exports}}
\]  

For all these terms presented in equation (2) it can be used the IEA statistical data.

In order to calculate the CI of the electricity supplied (post trade) in a country it is possible to use equation (1), considering in the denominator the result of equation (2), and in the numerator the value of total GHG emissions embedded in the electricity supplied, calculated according to equation (3):

\[
\text{GHG}_{\text{total}} = \text{GHG}_{\text{combustion}} + \text{GHG}_{\text{upstream}} + \text{GHG}_{\text{exported}} + \text{GHG}_{\text{imported}}
\]

Combustion and upstream GHG emissions are the same values used to calculate the CI of electricity produced in each country, the exported GHG is simply the product between the CI of electricity traded multiplied by the Upstream and combustion emissions.

Imported GHG emissions can be treated as

\[
\text{GHG}_{\text{imported}} = \Sigma (\text{GHG}_{\text{net from i-th Country}} \times \text{El}_{\text{Import from Country i}})
\]

where for each country it is necessary to consider the sum-product of all the amount of electricity traded (El. Import from Country “i”) and the respective Carbon Intensities (CI El traded Country “i”).

Table 1 shows the results of calculations for the different values of carbon intensity, calculated for each EU country (for the year 2013).

The order of the countries listed in Table 1 is the same as shown in Figure 1. Countries were presented according to the decreasing share of non-renewable sources in the generation of electricity.

Interesting are the results presented in Figure 2. The results from Table 1 have been added to the results presented in Figure 1. The percentage of electricity from combustion processes (in individual EU countries) are compared as well with the CO2 mass emission per kilowatt-hour by electricity production and its use (together with import) in every country.

The data primarily indicate that centralized electricity generation and distribution systems cause large losses in energy transmission - which means a significant increase in specific CO2 emissions (in g/kWh).

Electricity imports (especially if this energy is produced in the exporter's country from non-renewable resources), can lead to a significant increase in CO2 emissions "in the country that imports" electricity.

5. Electricity use by BEV’s operation

For the correct emission assessment related to the production and use of energy in e-mobility, it is necessary to know the electricity demand of electric vehicles (BEVs).

Based on the assumption that the emission related to the supply of electricity to the vehicle's charging point is known (Table 1), it is necessary to assess how much of this energy must be used to drive at a particular section of road.

The necessary data can be obtained from the appropriate tests (in the EU previously NEDC test and currently WLTP [4]) but it is known that the test results do not coincide with the data from natural exploitation [11].

Therefore, it is crucial to assess the operational energy “consumption” in the natural exploitation of vehicles (energy cannot be consumed – possible is the change of its form only – but as parallel to the historical term “fuel consumption” in following will be the term “energy consumption” used). It seems that for assessing the energy consumption in natural exploitation of BEVs in particular is the theory of cumulative energy consumption useful.

The theory of cumulative energy consumption was originally developed (as author work) to assess the cumulative consumption of fuel in the natural exploitation of ICE vehicles [5].

The usefulness of the theory has been repeatedly confirmed, also when powering the engines with various fuels [6, 7, 8, 9]. The main applications of the theory have been found in assessing the fuel consumption of urban bus fleets. Special software has been created for proper data collection (for obvious reasons, it will not be described here).
The energy consumption of a car in its natural exploitation is a random process. Energy is consumed in the "quantum" model. Energy quanta have a random size. Also, the time between the quantum of energy consumed is random.

Total amount of quanta of energy supplied to the car engine in the its operating period is called as cumulative energy consumption.

Energy quantum summation leads to determining the cumulative energy consumption. Energy consumption caused by the time \( t \) of the engine work, can be designated as

\[
CFC_c(t_d) = \sum_{i=1}^{n(t_d)} q_i = n(t_d) \cdot \bar{q}(t_d) \tag{5}
\]

wherein:

- \( CFC_c(t_d) \) - the cumulative energy consumption to the mileage \( t_d \)
- \( t_d \) - mileage
- \( q_i \) - i-th quantum of energy
- \( \bar{q}(t_d) \) - the average size of the quantum of energy used to the mileage \( t_d \)
- \( n(t_d) \) - number of the energy quantum used to the mileage \( t_d \)

To know the cumulative energy consumption to the mileage \( t_d \) should be familiar with the average size of the quants and the number of quantum of consumed energy to that mileage.

The way to reach these values has been presented in [1]. These publications also provide a way to obtain a mathematical model describing the cumulative energy consumption as a function of the vehicle's mileage.

The model has a form

\[
CFC_c(t_d) = \sum_{i=1}^{n(t_d)} q_i = n(t_d) \cdot \bar{q}(t_d) = c t_d^{a+1} \tag{6}
\]

The intensity of energy consumption is a mathematical derivative from equation (6), so it has a form

\[
CFC_c = ICFC_c(t_d) = \frac{dCFC_c}{dt} = c(a+1)t_d^a \tag{7}
\]

wherein:

- \( ICFC_c(t_d) \) - the intensity of cumulative energy consumption to the mileage \( t_d \)
- \( c, a \) - coefficients

Constants "\( c \)" and "\( a \)" equations (6) can be derived from data obtained from the use of vehicles in natural operation. Such data are collected by various institutions and individuals. One of a good database is from the website spritmonitor.de [11]. The advantage of this database is not only the large amount of data collected there, but also their widespread (and easy) availability. Data from this database will be used in further consideration.

Figure 3 presents operation data of the SMART Fortwo car No 641784. To determine the coefficients "\( c \)" and "\( a \)", data from the operation are necessary and sufficient.

After calculations, the following results are obtained

\[
c = 0.201467, \ a = -0.017827 \tag{8}
\]

and accordingly

\[
CFC_c(t_d) = c t_d^{a+1} = 0.201467 t_d^{0.992173} \tag{9}
\]

And

\[
ICFC_c = c(a+1)t_d^a = 0.197874 t_d^{0.017827} \tag{10}
\]

Six decimal places of coefficient values look a bit shocking. They were, however, deliberately entered. The author's experience shows that the more accurately the value of coefficients is given, the mathematical model is more adequate. On the other hand, in today's computing calculations, the accuracy of calculations results from the use of values with a much larger number of decimal places. These values are stored in the computer's memory and it does not matter how they are displayed on the screen.

Similarly, the results of the analysis but in the case of a TESLA S85 car (No. 733036) lead to data

\[
c = 0.212467 \text{ and } a = -0.003939 \tag{11}
\]

The models adequacy assessment (6) was carried out using the analysis of variance. The results are as follows (Table 2).

<table>

The observations number is in this case the same as the charging number.

The results are amazingly good. It was not expected that the correlation coefficients will be so high (it is worth recalling here that the maximum theoretical value of, for example, the R square (R²) coefficient is R² = 1). It is hardly surprising that the correlation coefficient has such a high value since the "measuring" points lie almost perfectly on the curve of the model.

A graphic illustration of the results obtained is shown in Figures 4 and 5. In this form presented results can be treated as a kind of energy footprint of the defined vehicle.
With the data from tables 1 and 3 is possible to achieve of CO₂ emission in each country of EU. The calculations results are here in the Figure 5 given.

**Fig. 5 CO₂ emission in the operation of BEV’s in countries of EU and also average for EU**

For the comparison in Figure 5 are the maximum emission of CO₂ for car fleets in EU for next year’s showing. These values are correct for NEDC but for the WLTP test they are only slightly lower.

The results of the calculations proved to be in line with expectations. On average, in the European Union it is already worthwhile to use electro vehicles (BEV’s) because CO₂ emissions are within the limits of the adopted standards for 2020. The use of small BEV’s already allows to meet the standards for 2025 today.

Figure 5 shows that in some countries, in order to get closer to the standards for 2020, it would be necessary to reduce CO₂ emissions by at least a half. This means that although any action is aimed at reducing energy consumption of vehicles have a sense, then the main burden of change should concern the change in energy production and distribution.

6. Conclusions

This paper presents two important methods for assessing the emission of electric vehicles
- an emission assessment method for generating and supplying electricity to battery charging points,
- a method of assessing energy consumption in the natural use of vehicles.

Both methods are shown in a static application - although there are no contraindications to use them together in dynamic applications, including emission forecasting.

The method of using both methods is presented on the example of CO₂ emission assessment resulting from the operation of battery electric vehicles.

Simulation research shows that there are already countries in the EU where the operation of electric vehicles makes sense. Especially when it concerns CO₂ emissions. Emissions below the standards for 2025 can be obtained there. Unfortunately, in many EU countries, the operation of BEV is associated with increased (in relation to present day) CO₂ emissions.

Because the high emission, in the first place, corresponds to the use of energy coming from non-renewable resources, together with excessive CO₂ emissions probably occur excessive emissions of nitrogen and sulfur oxides and a number of others, as well as heavy and radioactive metals. Even if the plants are equipped with appropriate exhaust gas treatment systems, there are no systems operating with 100% efficiency therefore emissions cannot be avoided.

Without changing the energy policy, and in particular the energy mix, introducing e-mobility is problematic.

TYPES OF MATERIALS USED FOR WINTER MAINTENANCE OF ROADS, EFFICIENCY AND INFLUENCE ON CORROSION OF ROAD FACILITIES

Eng. Kyuchukov N
'Todor Kableskov’ University of Transport – Sofia, Bulgaria, n.kyuchukov@abv.bg

Abstract: The report examines the work of snowmoving machines, the materials used for winter maintenance of roads, the implementation and the preparation for winter maintenance of the street network of Sofia Municipality. As well as a new approach to real-time operational decision-making to support the patentability of the street network in order to increase efficiency and reduce the areas of the boulevards, streets and municipal roads in winter. This will reduce the funds spent to maintain winter and reduce air pollution from the reduced number of street treatments and optimize the movement of snowmoving machines.

Keywords: WINTER MAINTENANCE, MATERIALS WAY OF ACTION IMPACT ON CORROSION AND ECOLOGY

1. Въведение

През последните години леда и снега по улиците и пътищата създават проблеми за тези, които ги използват. За минимизиране на проблемите свързани с поддръжката пътната инфраструктура, органите отговарящи за поддръжката на пътищата предприемат оперативни действия за отстраняване на снега и мерки за противодействие на хлъзгави пътища. От своя страна тези последващи действия оказват силно влияние върху безопасността, достъпността на превозните средства и пътни- потока. Оптимизирането на разходите за зимна поддръжка на пътища и улици трябва да бъде свързано с използване на материали щадящи околната среда, които сами по себе си са скъпи. Следователно, разработването на ефективни стратегии и методи за оперативни действия и мерките е въпрос на неотложност, както и събирането на знания за ефектите и разходите, които различните зимни стандарти предполагат за пътниците и пътните организации за поддръжка. Също така е важно да се разработят методи за ефективно измерване на постигнатите стандарти. Препоръчаните мерки трябва да бъдат обвързвани с вида и класа на пътищата от групата на междуселищните, както и от класа на улиците в населените места, като се обръне внимание на спецификата в план и профил на всяка улица, наличие или липса на отводнителни съоръжения, постоянна организация на движението с възможност за създаване на времена при екстремни ситуации, носеща способност на пътната конструкция, вид и състояние на пътното покритие, вид и състояние на пътната маркировка, интензивност на пешеходното движение. Тези данни са базови за вземане на решения при зимното поддръжане, съобразно атмосферните условия, материали, механизация и конкретни обекти от инфраструктурата.

2. Природни състояния които водят до замръзване на пътните настилки:

- Скреж
- Мъгла
- Обледеняване
- Снеговалеж, преобразуващ се в лед
- Леден дъжд

2.1. Скреж

Образува се в студените, сравнително ясни нощи и когато скоростта на вятъра е ниска.

Всички обекти излъчват инфрачервена радиация. Колкото по-топъл е обектът, по-голямо е инфрачервеното лъчение, което излъчва. Всички ние имаме известен опит с инфрачервена радиация; например, когато седим в стая в която е запалена камина, усещаме инфрачервеното лъчение, което излъчва огъня. Някои обекти излъчват инфрачервени лъчи по-добре от други. Например, земната повърхност е далеч по-ефективна при излъчване на лъчение от газовете в атмосферата. Областите са много добри в излъчването и поглъщането на инфрачервена радиация.

Фигура 1. Радиационно излъчване

При ясна нош земната повърхност излъчва инфрачервена радиация. Когато няма облаци, което да я спира, по-голямата част от тази радиация се губи в пространството. Някои това повърхността и въздухът в близост до нея се охлаждат бързо. Извън студената повърхност въздухът е по-топъл. По този начин, при студените и ясни нощи температурата е затопля с увеличаване на надморската височина - обратното на нормалната ситуация.
Когато температурата се увеличава с повишаване на надморската височина, това явление се нарича инверсия.

При облачни ниции, облаците действат като метеорологични оaeda, които забавят или предотвратяват загубата на инфрачервено лъчение (топлина) от повърхността и по този начин охлаждането е далеч по-малко. Одеялата ни затоплят, забавяйки загубата на топлина от нашата тела - облаците работят по подобен начин, с изключение на това, че намаляват количеството топлина, напускаща повърхността. Силните ветрове също работят срещу повърхностното охлаждане, тъй като ветровите условия "разбуждат" атмосферата и смесват част от отоплени въздуха от земята на надолу.

Във въздуха се съдържа голямо количество водна пара. Водната пара е невидим газ: водата може да се види само в началото на зимния сезон или след период на топла време. Водната пара в атмосферата остава под форма на невидима пара. Облака работят по подобен начин - при преминаване върху път, който е охладен до температурата на замръзване, на пътната настилка е над 0 С.*, тъй като въздухът се кондензира във водни капчици или ледени кристали.

2.2. Мъгла
Често се образува при студени, ясни нощи, когато температурите падат до температурата на точката на настилката. Мъглата съдържа големи количества пара във въздуха, които при преминаване върху път, който е охладен до температурата на замръзване, образуват роса, но ако температурата е над нула градуса, розата се потъва в топъл въздух.

3. Предварителен анализ
Пред започването на зимата трябва да се направи обстоятелен анализ на пътната инфраструктура която ще бъде поддържана. В този анализ трябва да се имат предвид:

3.1. Местата през които преминават пътната настилка.

- Изстиването на пътната настилка в началото на зимата отнема дни или седмици. Въздухът се изстива и формира ледена покривка.

2.4. Леденият дъжд
Образува се при валеж, падащ при отрицателна температура на въздуха и наличие на температурна инверсия. В долния тропосфера в близост до земната повърхност въздухът е студен, а над него има слой от по-топъл въздух. В топлия въздушен слой дъжд е под формата на малки щурани със съдържаване на вода в сферни капчици. При продължително понижаване на температурата на въздуха розата се замръзва на пътя. След няколко минути това може да бъде бързо и тежко, и дебел слой лед да се образува за няколко минути.

2.3. Обледеняване на пътните настилки
Появява се когато температурата на пътната настилка е над 0 С, щучата е мокра от отворена вода, която при преминаване върху път, който е охладен до температурата на замръзване, образувото водата може да бъде бързо и тежко, и дебел слой лед да се образува за няколко минути.

3. Предварителен анализ
Пред започването на зимата трябва да се направи обстоятелен анализ на пътната инфраструктура която ще бъде поддържана. В този анализ трябва да се имат предвид:

3.1. Местата през които преминават пътната настилка.

- Изстиването на пътната настилка в началото на зимата отнема дни или седмици. Въздухът се изстива и формира ледена покривка.

2.4. Леденият дъжд
Образува се при валеж, падащ при отрицателна температура на въздуха и наличие на температурна инверсия. В долния тропосфера в близост до земната повърхност въздухът е студен, а над него има слой от по-топъл въздух. В топлия въздушен слой дъжд е под формата на малки щурани със съдържаване на вода в сферни капчици. При продължително понижаване на температурата на въздуха розата се замръзва на пътя. След няколко минути това може да бъде бързо и тежко, и дебел слой лед да се образува за няколко минути.

2.3. Обледеняване на пътните настилки
Появява се когато температурата на пътната настилка е над 0 С, щучата е мокра от отворена вода, която при преминаване върху път, който е охладен до температурата на замръзване, образувото водата може да бъде бързо и тежко, и дебел слой лед да се образува за няколко минути.

2.3. Обледеняване на пътните настилки
Появява се когато температурата на пътната настилка е над 0 С, щучата е мокра от отворена вода, която при преминаване върху път, който е охладен до температурата на замръзване, образувото водата може да бъде бързо и тежко, и дебел слой лед да се образува за няколко минути.

3. Предварителен анализ
Пред започването на зимата трябва да се направи обстоятелен анализ на пътната инфраструктура която ще бъде поддържана. В този анализ трябва да се имат предвид:

3.1. Местата през които преминават пътната настилка.

- Изстиването на пътната настилка в началото на зимата отнема дни или седмици. Въздухът се изстива и формира ледена покривка.

2.4. Леденият дъжд
Образува се при валеж, падащ при отрицателна температура на въздуха и наличие на температурна инверсия. В долния тропосфера в близост до земната повърхност въздухът е студен, а над него има слой от по-топъл въздух. В топлия въздушен слой дъжд е под формата на малки щурани със съдържаване на вода в сферни капчици. При продължително понижаване на температурата на въздуха розата се замръзва на пътя. След няколко минути това може да бъде бързо и тежко, и дебел слой лед да се образува за няколко минути.
блокират загубата на инфрачервена топлина в пространството. Ето защо паркираните автомобили под дървета рядко измръзват. От друга страна, ако пътната настилка замръзне и се покрие с лед, засичването на дървета или хълмове може да забави топлението до късно сутринта или леда да се задържи и през деня. Редица фатални злополуки са настъпили по пътищата, когато шофьорите навлизат неочаквано в заледени сенчести участъци. Критичното време за заледяване на пътната настилка, засенчена от хълмовете, е особено характерно за високопланински пътища – пътища в ПП Витоша/са часовете преди и след залез слънца.

Фигура 4. Сенчести участъци на пътна настилка

В участъците, в които пътят преминава над магистрални водопроводи и газопроводи, пътната настилка замръзва в резултат ниската температура на движещите се през съоръженията флуиди.

Фигура 5. Магистрален водопровод под улично платно

3.2. Топлинно картографиране

Необходимо е изготвяне на топлинно картографиране на пътната инфраструктура, която ще бъде поддържана. Това се прави с цел оптимизиране на използваните реагентни материали при зимния период.

3.3. Оптимизация

Оптимизиране маршрутиите на движението на снегопочистващите машини от местостоянките (базите) до участъците, където ще се обработва, ще доведе до намаляване на вредните газове отделящи се от снегопочистващите машини.

Фигура 6. Графично изображение на топлинно картографиране.

4. Материали използвани при зимно поддържане.

4.1. Промин пясък – предимства: естествен и евтин материал, особено полезен при замръзнала пътна настилка (създава необходимото сцепление); недостатъци: не топи снега и леда. Необходимо е почистване на пътната настилка от пясъка използван през зимата. Утаяване в отводнителните съоръжения на пътната инфраструктура, което води до ограничаване на тяхната проводимост.

4.2. Натриев хлорид (NaCl) – предимства: евтино и широкоразпространено средство за обезледяване; недостатъци: не е достатъчно ефективно, особено при температури под -6°С, при които то спира своя ефект, причинява сериозни щети на обкръжаващата пътна растителност, може да замърси водната повърхност, както и изтощението на водата и не на последно място - има силно корозийно действие върху бетонови и метални конструкции.

4.3. Калциев двухлорид (CaCl2) – предимства: по-бързо първоначално топене на ледовете, по-дълго действие като предотвратява повторно заледяване, ефективен също и при по-ниски температури, увеличава ефективността на NaCl, ако се използват заедно, намалява разходите, тъй като се намалява използваните материали, по-ефективен при по-широк просперитет на нива на влажност; недостатъци: по-скъп от натриевия хлорид.

4.4. Магнезиев двухлорид (MgCl2) – предимства: имат най-голяма способност да привлича и задържа влагата от неговото обкръжение, ускорява процеса на разтваряне и разтопяване, не изисква допълнително почистване на настилката след прилагането му, не замърсява въздуха, недостатъци: многобройни проучвания показват, че MgCl2, когато е използван като делител, причинява много по-тежко влагане на бетона, отколкото NaCl или CaCl2.
5. Заключение:

От направеното изследване се установи, че доброто познаване на пътната инфраструктура, природните явления и качествата на използваните реагенти води до:

1. Добро управление в реално време на снегопочистващите машини, вида и количеството обработки.
2. Редуциране на разходите.
3. Намаляване на количеството отделяни фини прахови частици от оптимизираното движение на снегопочистващите машини и оптимално използване на химически реагенти.

QUALITY CONTROL OF MULTI-PASS WELD BY MEANS OF ACOUSTIC EMISSION

Chairman of the Board of TTS LNK INDUSTRIES, RIGA, Latvia¹, Riga Technical University Institute of Civil Aviation, RIGA, Latvia²,
Riga Technical University Institute of Civil Aviation, RIGA, Latvia³

Abstract: The article proposes a method of assessing the quality of multi-pass weld by acoustic emission. The AE method involves the identification of developing defects at the stage of stress changes in the material, as well as in the statically loaded state. In the process of control two independent data collection systems were used, which worked in the process of testing synchronously. The selected method of control of the object has a number of advantages over other methods of NDT.

KEYWORDS: ACOUSTIC EMISSION, WELDING JOINTS, PROPAGATING DEFECTS, DATA ACQUISITION SYSTEM.

Introduction
Currently, it is more and more popular the NDT method of welding structures elements technical condition assessing by the physical principles of acoustic emission. The main advantage of this method is its integrality without binding at the first stage to a specific place and fixing the health as "there is a DEFECT-no DEFECT" in a certain zone. After that, the decision is made quickly, for example, in the control of multi-pass welds in thick-walled structures, to eliminate defects with a minimum amount of metal sampling. However, this method requires real-time analysis and multi information that is coming in with high intensity, which is not always feasible. So there is the risk of losing some data on the further study of the defect, its nature, root cause and level of danger (maintainability)[1].

Research technology
The object of the research is multi-pass welding seals as butt straight joints of the bridge support pylon section (Fig. 1). The object of study is made by welding cylindrical cones of steel grade S355NL - analogues (USA A656, Russia 17Г1С, 17ГС). After welding, the quality is usually controlled by traditional non-destructive testing: visual, magnetic, ultrasonic, and radiographic.

AE data acquisition system
With the aim of obtaining acoustic emission data during the checking, there are used two independent from each other data acquisition systems, which operated simultaneously in the testing process (see figure 2, 3):

1. AE data acquisition system Lel / A-Line 32D (DDM) / - DIGITAL A-Line 32D. This is multi-channel AE data acquisition modular system

Fig 2. Portable AE data acquisition system A-Line32D

2. Mobile data acquisition system Physical Acoustics Pocket AE with outer preamplifiers 40dB

Fig 3. Portable AE-Station Pocket AE-2

The Pocket AE has only one recording line. The pickup gauge has been installed on outer surface of test object. (Fig. 4/1, left).
The A-Line System has two AE signals recording lines: the first pickup gauge has been installed on the outer surface of test object (Fig. 4/2), and the second - on the inner surface (Fig. 4/3), nearby the welding seal. [3]

Fig 4. The pickup gauges disposition on the test object.

Each AE pickup gauge has its own channel line and has been mounted on he surface by magnetic holder.
The test program included three stages
1. Lifting the object from the support with a crane
2. Keeping the object for 10-12 minutes
3. The descent of an object on a support
The AE method assumes the identification of propagated defects at the stage of stress changes in the material, as well as in the statically loaded state.[2] Changing the load is occurred during the change in the direction of deformation of the object. The test object has round in section, mass near 2 tons. Under its dead weight the pressed and bending loads are originated along the vertical axle.

(Fig 5.)

Fig. 5. The test object section deformation mode, then it sits on surface (left) and hangs (right) .
Then hang position the mode of load is changed. Under dead weight the pressed and bending loads are originated in horizontal axle of test object. Under the load changing any defects in existence generate the AE signals. Inspecting the AE characteristics, such as dynamics, amplitude etc., it is possible to reveal, identify and, if necessary, to locate the defect in test object. After the lifting stage (12 sec), there is the static holding stage during 600 sec. All the time AE signals have been recorded. Some detected AE signals have proved the existence of probably AE origins. During final checking stage the test object is moved down on supports in horizontal state. The load changing occurs in opposite order, than in the first stage. The unbend and spread stresses changes the compressed and bending ones. Also the AE signals are recorded.

Results of AE NDT

The picture of AE impulses during the experiment #1 (until the section of test object was rotated to 90°), recorded by Mistras Pocket AE-2, channel #1. The Test Results (the data line of Pocket AE)

Fig. 6. Left: the AE intensity and amplitude versus time

Right-upper: AE-summing versus time;
- center: AE impulses amplitudes frequency;
- down: AE intensity versus time

Fig. 7. The Test object loading and AE intensity. Experiment #1

The test program included three stages
1. Lifting the object from the support with a crane
2. Keeping the object
3. The descent of an object on a support

Fig. 8. The Test Object loading and AE intensity during Test Object lifting (experiment #1)

From the first second the acceleration of the AE-intensity growth is observed (α-criteria) [5]. From the second 13 of the beginning of test object holding-off two step-up stages of AE-intensity (Pocket AE) are observed (secc. #640 and #670).

After the first experiment, the test object was rotated by 90 grad around the longitudinal axis and the tests were repeated. It is necessary in order to identify possible defects that did not revealed due to a possible difference of the mutual direction of the proposed crack contour and the vector of the applied load.

The test object checking results (A-Line System).

Fig. 10. Diagrams of AE data plots (A-line system, first experiment, till test object rotation.).

Fig. 11. Diagrams of AE data plots (A-line system, second experiment, after test object rotation.).

Fig. 12. The Test object loading and AE intensity. Experiment #1 (A-Line).

Comparing the A-Line and Pocket AE sistems pickup data their agreement is observed. During experiment following AE-signals data are registered.
- amplitude,
- intensity,
- AE impulses summing
At the stages of test object lifting and descending on the support AE average (dozens of impulses per second) intensity was observed. The nature of the total AE-summing is different. At the stage of lifting, the total AE diagram has only one characteristic pronounced break-point, while at the stage of descent — two
stages. This may indicate the presence of fine heterogeneity in the material of the object.

At the stage of test object holding no intense emission was observed. Single events that occur within 600 seconds of the experiment do not carry information about the presence of dangerous heterogeneity that propagated over time. This emission is normal for a homogeneous material. Additionally the welded sample was checked by visual and ultrasonic method

Results of visual and ultrasonic NDT checking

Under visual-measuring check of welded joint defects have been not identified. Ultrasonic scanning was carried out along the entire length of the weld, after the closing of welding within up 40 hours [4]. The results were obtained by using USM 35 XS ultrasonic flaw detector. Angle beam transducers of transverse waves are used to scan, the dimensions of the piezo-element 14x14 mm, frequency 2 MHz, with input angles of 45º, 60º and 70º, and also the direct transducers of longitudinal waves were used. The dimension of the piezo-element 6x20mm, a frequency of 4 MHz and a piezo-element with a diameter of 24 mm 2 MHz, the tuning was performed on the lateral drilling with a diameter of 3 mm. In the zone specified by acoustic emission checking, the indication at a depth of 12 mm with a signal amplitude +3 dB conditional length of 10 mm in the analysis of the characteristics of the signal was revealed, it was determined as the indication of the defect spherical shape

See Fig. 13.

Fig. 13. The pickup data of ultrasonic NDT

Summary

The proposed method of the object checking has some advantages over methods of NDT. The time of preliminary assessment of the technical state of the object practically coincides with the time of the experiment. Taking into account the preparation and tuning of the equipment, it took about 30 minutes to check the object. The method does not require the use of dyes, powders, ionizing radiation. The inspection process does not involve the use of consumables or cleaning of the object after the experiment. At the same time, short-term use of lifting or loading equipment (crane, Jack, etc.) is required.

Tests have shown the presence of heterogeneity of the material, manifested under dynamic loads, but not detected in a static state. To localize this heterogeneity a re-AE-experiment with the number of sensors not less than 4 is required. Such experiment is possible with the use of the A-Line 3D system and does not require additional AE equipment. For classification of heterogeneity to the class of hazardous or non-hazardous, other NDT methods are required, which is confirmed by the data obtained as a result of ultrasonic scanning.

REDUCING THE ENERGY INTENSITY OF MULTI-PRODUCT MACHINERY PRODUCTION BY IMPROVING THE CORE PRODUCTION INFRASTRUCTURE

V.G. Abrahamyan
Russian-Armenian University
Yerevan State University
a.vahram@mail.ru

Abstract: Multi-product machinery production forms a machine park of an industrial organization, so the finished products must provide high-quality and economic indicators while using them in productions. The problem of increasing the level of production efficiency is analysed in such organizations depending on the improvement of the basic production infrastructure. The new, quantitative indicators are presented, which help justify the interrelations of material, labor and energy production costs. The necessity of implementation of innovative technological processes at the preproduction phases is justified, which allows to reduce the level of material intensity, labor intensity and energy intensity of production and increase the efficiency of the production organization.

KEY WORDS: MECHANICAL ENGINEERING, PRODUCTION PHASES, INFRASTRUCTURE, MATERIAL INTENSITY, LABOR INTENSITY, ENERGY INTENSITY.

In order to create a powerful and efficient economy, it is necessary to form a corresponding industry which will provide the necessary basic resources to the other sectors of the economy and form the appropriate material and technical base. The harmonious implementation of these processes in space and through the time enables to form a kind of structure which guarantees the balanced development of all sections of the economy and promotes the effective solution of existing social and economic problems. It is necessary to ensure the rapid and progressive development of multi-product machinery production (machine-tool construction) as it forms the basic tools of industrial enterprises and creates the necessary mechanical assembly for the production and technological processes. For the timely solution of the problems, it is necessary to ensure the efficient and competitive activity of a multi-product machinery production organization (hereinafter - manufacturing company). For this reason, a manufacturing company must systematize all the integrated processes that are implemented from the formation and design of ideas (R&D, technical and organizational preparation of production) to the production and realization of new products.

For this purpose, the manufacturing company by using the marketing division's instruments included in its logistic service, studies the changes in the market on the basis of which the necessary information base is formulated for innovation policy and restructuring the manufacturing company's infrastructure.

In the framework of the innovation policy realization, in the manufacturing company must be developed and realized the upgrade of the range of the corresponding innovation programs' products (improvement of manufacturing products, implementation of new products) and introduction of new technological processes. In order to implement the developed strategic plans, the manufacturing company needs to carry out the reconstruction of production and technological and organizational processes which improve the existing production infrastructure and the new technological processes and new production methods are implemented very fast and efficiently.

Multi-product machinery production, being the main source for the production of machinery and equipment, promotes the increase of the level of labor productivity in the other sectors of the economy. The technical re-equipment of production, the application of new advanced production and working methods are the basis for the increasing the manufacturing productivity and expanding the segment of the manufacturing company in the market.

The improvement of the level of productivity and qualitative indicators of the finished products, produced in multi-product machinery production, is one of the main factors in reducing the intensity and increasing the quality of products which are produced in the practical production by using them.

The correct formation of the main production infrastructure has the key role for increasing the productivity of multi-product machinery production which is important in generating the production costs. The improvement of the main production infrastructure of manufacturing company gives an opportunity to raise the level of production effectiveness by reducing of production costs. In multi-product machinery production the efficient use of material and labor resources and the reduction of their costs plays the key role in reducing the production costs, as they have the major share in total production costs.

The results of the conducted research show that in multi-product machinery production, the full intensity has the following structure: technological intensity is 60-65%, service intensity is 15-20%, maintainance intensity is 15-20%. In multi-product machinery production, first of all, it is necessary to accurately predict and justify the value of technological labor intensity, as it is the main strategy for increasing the labor and production productivity.

In multi-product machinery, the level of technological labor intensity depends on the level of material intensity of production but the level of the energy intensity of production in its turn depends on the level of labor intensity of production. Therefore, in the production should be used such kind of production and technological processes which will first of all reduce the level of material intensity of production.

The results of the conducted research show that in multi-product machinery production the main production phases technological intensity has the following structure: preproduction phase - 15-20%, design - 45-55%, assembly - 20-25%, other technological processes - up to 10%. Hence, the major share of technological labor intensity (about 60-70%) has preproduction and design labor intensity phases. So, we could say, that the value of these phases directly depends on the level of material intensity of production. The production phases that are mentioned in the industrial organization are also energy intensity.

The level of labor intensity of design phase is determined by the level of the technological processes progress, which are used in the preproduction phase. At this stage the use of innovative technological processes gives an opportunity to increase the degree of the preforms' output. As a result, their shape and size is brought closer to the shape and size of the finished parts, minimizing the volume of waste disposal. This helps to reduce the level of material and labor intensity, which leads to the decrease of energy costs in the manufacturing company.

The analysis shows that the level of labor intensity directly depends on the level of material intensity and the level of material intensity depends on the degree of accuracy of the used preforms. It is justified by the modification of the well-known formula for determining the labor intensity in the design phase which is illustrated as follow:

\[ t_{ij} = \frac{m_{ij} - m_{ij}}{n_{Shb}} \]  \hspace{1cm} (1),

where the numerator is the volume of waste disposal, the denominator is a constant value for the given type of preform.\(^1\)

\(^1\) Abrahamyan V. Increasing the effectiveness of multi-product machinery production through the management of the organizational and innovative processes. Yerevan, 2010, p. 141
We can conclude, that the value of technological labor intensity of designing is directly proportional to the value of the preform mass (or waste disposal).

It is necessary to use progressive technological processes for reducing the value of material intensity in the preproduction phase, which will give an opportunity to minimize the volume of waste disposal. As a result, the mass of used materials will be reduced as well as the level of energy and labor intensity in the design phase.

Labor intensity of each part of preform included in the finished product structure in the preproduction phase can be determined by the following formula:

\[ t_{1ij} = A_{ij} \left( \frac{m_{ij}}{K_{ij}} \right)^{\gamma_i} \]

where \( t_{1ij} \) is technological labor intensity of \( i \) part of preform in \( j \) production with technological process, \( m_{ij} \) is the net mass of \( i \) part, the preform of which is made by \( j \) technological process, \( K_{ij} \) is the coefficient of the use of material of \( i \) part in the case of making the preform by \( j \) technological process, \( K_{1ij} \) is the coefficient, which considers the impact of production volume at \( t_{1ij} \), \( K_{2ij} \) is the coefficient which considers the impact of preform's degree of complexity at \( t_{1ij} \).

The value of technological labor intensity of one machine set of the manufactured finished product can be determined by the following formula:

\[ T_{p} = \sum_{j=1}^{J} \sum_{i=1}^{I} t_{1ij} = \sum_{j=1}^{J} \sum_{i=1}^{I} A_{ij} \left( \frac{m_{ij}}{K_{ij}} \right)^{\gamma_i} K_{ij} K_{2ij} \]

where \( j = \sum_{j=1}^{J} K \) are the possible types of technological processes for creating preforms, \( i = \sum_{i=1}^{I} N \) is the quantity of parts included in the structure of the finished product, the technological processes of their preforms creating and designing are made in that manufacturing company.

In the preproduction phase, the power energy cost per product unit can be determined by the following formula:

\[ E_{1} = \sum_{j=1}^{J} \sum_{i=1}^{I} t_{1ij} N_{ij} K_{ij} K_{2ij} a \]

where \( N_{ij} \) is the total nominal capacity of the engines in the machinery and technological equipment used in production of preforms of one machine set parts of finished product with the various technological processes in the preproduction phase, \( k_{ij} \) is the coefficient of nominal capacity use of machinery and technological equipment, \( a \) is the tariff of electricity.

By determining the power energy cost before the implementation of advanced technological processes, for creating the preforms in the preproduction phase of production and after the implementation of these processes, the change in the amount of power energy cost caused by the use of innovative technological processes can be determined.

\[ E_{2} = e^{\sum_{j=1}^{J} \sum_{i=1}^{I} \sum_{m_{ij}} \left( \frac{m_{ij}}{K_{ij}} \right)^{\gamma_i} K_{ij} K_{2ij} a} \]

The conducted research results show that in the design phase of multi-product machinery production, the value of technological labor intensity for one machine set of manufactured finished product is determined by the following formula:

where the first component is the absolute term (\( e^{2.71828} \),

THE RESEARCH PECULIARITIES OF PARAMETERS AND CHOICE OF AGRICULTURAL MACHINES IN PEDagogICAL TECHNOLOGIES FOR INNOVATIVE PROJECT ACTIVITY IN TRAINING AGROENGINEERS

Candidate of Technical Sciences, Associate Professor Viktor Pryshliak
Ukraine, Vinnytsia National Agricultural University
viktor.pryshlyak@i.ua

Summary. The structural-logical model of training of future specialists in agroengineering for innovative project activity has been developed on the basis of a systematic comprehensive study of the theoretical course of agricultural machines, the deepening of the students' scientific work on the development of supporting and moving elements of machine-tractor units, including pneumatic tires. The samples of individual fragments from the algorithm and the method of calculation of wheels used in the educational process are provided and the general and professional competencies of the agroengineer are created, especially during the implementation of future specialists in agro-industrial production of higher education courses in the course of master's and master's studies. It is noted that the training of agroengineers for innovative project activities is carried out in accordance with the Law of Ukraine "On Higher Education" and the standards of higher education of Ukraine. The influence of interdisciplinarity in the system of cross-cutting project preparation on the readiness for implementation of production practical tasks is investigated. It is confirmed that the support-run elements of aggregates in the conditions of complex terrain contribute to the development of erosion processes and negatively affect the soil fertility. Any tire better satisfies the condition of permissible wheel pressure on the soil if the air pressure in the tire is low. Improving the technological process of manufacturing tires for agricultural purposes allows them to ensure their quality, reliability and operational safety.

KEYWORDS: WHEEL TIRES, AGRICULTURAL MACHINERY, TECHNOLOGY, PROJECT TRAINING, PROJECT ACTIVITY, STUDYING PROCESS, THEORY

Introduction.
Science and education are closely interconnected and able to develop effectively in a single integrated system of scientific, methodological and pedagogical activities. Educational process is an intellectual, creative activity of scientific and pedagogical workers, students, practitioners and other interested subjects in the sphere of higher education and science [1].

The training of future agroengineers is based on the formation of professional competences in a harmoniously developed personality capable of solving various tasks of production activity. The object of the study and activities of the agroengineer are the phenomena and processes associated with the effective functioning of agricultural machinery and mechanized technologies in agro-industrial production [2]. The educational process of students of the specialty "Agroengineering" is aimed at training specialists capable of solving professional specialized tasks and applied problems related to the use of agricultural machinery in mechanized production technologies, primary processing, storage and transportation of agricultural products, technical service of mechanization facilities, etc.

In the structural and logical scheme of training future agroengineers, the basic discipline is "Agricultural machines". Students learn about the structure and principle of operation of agricultural machines, regulation and adjustment of them for optimal modes of work, as well as the theoretical basis of technological processes of working bodies, the method of development and designing new and improving existing structures [3]. Studying discipline in addition to classroom activities involves the independent performance of course work, the purpose of which is the technological development of the design of agricultural machinery or its units, or the improvement of existing machines to ensure the implementation of mechanized production processes of growing crops and improving the operational, economic and environmental performance.

The main scientific directions of the master's work in the field of agroengineering are to increase the productivity of aggregates, expand their versatility, combine energy resources with other implements and ensure their reliable handling, minimize the negative impact on the environment and soil, improve the working conditions of machinery, as well as traffic safety. Agricultural machine-tractor aggregates are driven across the field by overwhelming majority by means of a wheeled driving system. The processes that occur when the wheels interact with the soil, affect not only the performance of the machines, but also the properties of the soil, as the object of cultivation and the environment of cultivating crops.

Prerequisites and means for solving the problem.
For a long time, scientists have been engaged mainly in the study of the processes of interaction of the running system with the soil and traction-coupling properties of machines. Regarding the deformation of pneumatic tires of agricultural wheels, these issues are not sufficiently studied.

The problem issues related to the design of agricultural machinery, preparation of agroengineering specialists for the project activity, including the features of substantiation of parameters and selection of tires of wheels, are not sufficiently studied. In [4], the main components of the preparedness for the project activity of the agroengineer as a specialist are presented, which are united in physical and mathematical, general technical and special blocks and general and professional competences, which should be mastered by the bachelor of specialty 208 "Agroengineering". For example: to design equipment and equipment of production areas, agricultural machines, their knots, mechanisms, various connections; carry out standard design calculations of knots and parts of machines and non-standard equipment; rational assembly of machine aggregates in existing production lines of crop and livestock production; to determine the technical condition of tractors, cars and aggregates of complex equipment [2], to optimize transport processes, etc.

In [5] presented an innovative system of scientific and methodological developments that affect the formation of special professional competencies of agroengineering. The basis of this system is the latest textbooks, manuals, monographs, programs and other teaching materials, as well as advanced pedagogical technology of training, which is based on the progressive, phased development of the future specialist's readiness for the project activity. Such pedagogical technology of training provides a comprehensive, comprehensive formation of professional competencies of agroengineering in accordance with regulatory requirements and standards of education, including [1, 2]. Students'
scientific activity, which is based on the development and modernization of agricultural machinery, plays an important role in the design training. It was noted [5] that the first voluminous work of the student in the educational process is the course work on the discipline “Agricultural Machines”. Its successful implementation is a solid ground for effective and effective graduate design, writing master’s thesis.

The general issues of the theory of design training were studied deeply by: Bryukhanova N.O. [6], Kolesnikova I.A. [7], Gorschakov-Siberian M.P. [7], Nychalko N.G. [8], Zyzun I.A. [8], Goncharenko S.U. [8] et al. The theory, methodology and practice of design training for agroengineering, including in view of the design of agricultural machinery, were studied and investigated: Bendera I.M. [9, 10, 11], Duganets V.I. [12], Pryshliak V.M. [4, 5, 13] and others. Also, the questions of improving the methodology of preparing future engineers are devoted to the work of A. Asherova, O. Kovalenko, M. Lazareva, D. Chernenlyk, P. Yakovychina, and the methodological aspects of the future of agroengineering have been reflected in the scientific researches of I. Buzik, A. Demin, S. Daukalis, A. Esaulev, P. Luzan, V. Manke, I. Palamara, S. Pastushenko, V. Yaroshenko, transformation of independent educational activity into readiness for professional self-development by means of technologies of personally oriented education – is reflected in the monograph Bondar M.M., Zhuravsky L.M., Ostapenko E.O., Pryshliak V.M., Kutseko A.G. [14].

Actual issues of studying the design, operation of tires, reducing the harmful effects of the effect of running systems of the machine, tractor, unit on the soil are devoted to the work [15, 16, 17, 18], and their production – [18, 19].

**Solution of the examined problem.**

As noted in [5], the theory and project practice of preparation for future agroengineering involves the widespread use of a scientific component in the educational process during classroom classes, independent work of students. The scientifically substantiated cross-cutting, interdisciplinary, sequential and phased development of agricultural machinery involves achieving a high quality learning outcomes and innovative technology development.

Apart from the fact that students during their studies at the institution of higher education take part in research processes, conferences, construct and model the means of mechanization, they are to complete the term paper at the 3rd year, and in the master’s degree - a master’s degree. Here, students mainly count, design and study the working bodies of agricultural machines. However, there are works in which auxiliary but very important nodes, mechanisms or systems of machines are presented. The same applies to the support and running elements of agricultural machines, including wheel tires.

The type of wheel tires of agricultural machines should be selected, taking into account the permissible action of the wheels on the soil. Preferably the ecological pressure limit of the wheels on the soil, depending on its type and state, is taken at a pressure of 0.1-0.15 MPa.

First, for one of the circles [3], it is necessary to determine the radial load of the wheels on the soil (kN), which will correspond to the required lifting capacity of the wheels of the machine, using the formulas:

\[ G_2 = 10^{-3} aQ_a / n_2L, \]  
\[ G_1 = \sqrt{(10^{-3} gQ_a - n_2G_2) / n_1}, \]

where:
- \( a \) – center of gravity of the machine, kg [3];
- \( Q_a \) – operating mass of the car relative to the rear axle, m [3];
- \( g \) – acceleration of force weight, m/s²;
- \( n_2 \) – number of front wheels [3];
- \( L \) – longitudinal base of the car, m [3];
- \( n_1 \) – number of rear wheels [3].

After receiving the radial load of the wheels on the ground, you can proceed with the selection of the necessary tires, following this sequence of actions. First, using the calculated payload capacity of the rear and front wheels (\( G_1 \) and \( G_2 \)), for tabl. I choose a tire capable of providing their payload, i.e.

\[ G_2 ≥ G_1, \quad \text{and} \quad G_2 ≥ G_1. \]

It has been established that any tire will better satisfy the achievement of permissible wheel pressure on the ground \( P \), if the air pressure in the tire is low. After the previous choice of tires, under its designation in the table. 2 linear sizes are selected: outer diameter \( D_s \) and width of the tire \( a_w \).

After that, it is checked whether the selected tires are provided to the given ecologically permissible pressure on the soil, using the formula

\[ G_0 = 0.12\pi P_{\text{in}} P^2 a_w^2 D_s^4 / \left( \pi^2 P_{\text{in}} a_w^4 D_s^4 + 4 P^2 \sqrt{D_s a_w} \right), \]

where \( P_{\text{in}} \) – tire pressure, MPa (Table 1); \( P \) – permissible wheel pressure on the ground, MPa [3]; \( a_w \) – width of the tire (for cars working in intermediate rows, the width of the tire must be less than the width of the row), cm (Table 2);

\( D_s \) – external diameter, cm (Table 2).

In tabl. 1 shows only data for air pressure in the chamber up to 0.2 MPa. Tires with pressures greater than 0.2 MPa are not recommended for use on field machines.

If the calculations

\[ G_0 < G_1, \quad G_0 < G_2, \]

then it is necessary to choose the bus with other parameters; and if the tire could provide a condition

\[ G_1 ≥ G_2, \]

it is impossible to pick up, the wheel must be taken with twin tires. In this case, the number of tires for the wheel is determined from the ratio

\[ Z = G_1 / G_2. \]
Then repeat the same calculations for the second scheme of the wheel drive of the car. The numbers for the tire, for example, 5.0-10, reflect: the first figure is the width of the profile of the tire in inches, the second is the tire’s diameter on the disc in inches.

As an example, according to such an algorithm, students of the 3rd year of specialty 208 “Agroengineering” conduct substantiation of parameters and choice of tires, performing course work on the discipline “Agricultural machines”.

During the study in the magistracy, future specialists in agroengineering conduct theoretical and experimental research at a higher scientific level. Let’s give an example of conducting such researches for wheels of agricultural machines during their movement in the field.

The processes of interaction of running systems with the soil depend on its mechanical properties, that is, resistance, deformation and destruction. A large amount of experimental data on the patterns of deformation and destruction of soil has been accumulated. But they are of a different nature due to the diversity of soil types, conditions and methods of measurement, and the lack of standardized methods for the integrated assessment of mechanical properties. The use of this data to develop methods for forecasting mechanical properties is not possible. This is due to the large number of proposed empirical formulas and models of deformation of soil [15].

In order to evaluate the interaction of the running system with the soil, the regularity of its compression and displacement is determined by the processes of formation of the track (track) and traction (traction) formation. These patterns are determined by the corresponding displacement of the deforming (dies).

The diagram of the interaction of the rigid wheel with the soil during rolling in a driven mode is shown in Figure 1.

![Fig. 1. The scheme of deformation of the soil [15]](image)

Observations show that the deformation of the soil by a moving wheel at different time points extends predominantly to the normal to the rim. Accordingly, the relative deformation $e$ and the rate of deformation $\dot{e}$, elemental volumes in the sectors corresponding to the corners, $d\varphi$ to which all its array is divided into angles $\varphi^0$ contact and thickness $A$ of the active layer (deformed) can be represented as follows [15]:

$$e = \frac{z_0}{l_0} \left(1 - \frac{\cos \varphi}{\sin \varphi} \right),$$

$$\dot{e} = -\omega \frac{z_0}{l_0} \cos \varphi \frac{\sin \varphi}{\cos^2 \varphi}.$$

where $z_0$, $l_0$ – the dimensions are shown in the diagram; $\varphi$ – the value of the contact angle; $\omega$ – angle of rotation of the wheel.

Normal wheel load $Q$ and longitudinal strength $F$, necessary to overcome the rolling resistance, due to the processes of interaction of the wheel with the soil, are equal to the sum of the normal and tangential elementary soil reactions

$$Q = \int_{\varphi_0}^{\varphi} \sigma \cos \varphi R_0 \, d\varphi; \quad F = \int_{\varphi_0}^{\varphi} \sigma \sin \varphi R_0 \, d\varphi,$$

where $\sigma$ – contact voltage (elementary soil reaction) $B$ and $r_0$ – contact width and wheel radius.

To solve these equations, it is necessary to use the analytical relationship between voltage and deformation.

The deformation of the soil (its elementary volumes) is completely reflected in the Kelvin model, to which the rheological equation corresponds:

$$\sigma = E_2 (\varepsilon + \dot{\varepsilon}),$$

where $E_2$ – deformation module; $\varepsilon$ – time after action

(viscosity ratio $\mu_2$ to the deformation module) $(\dot{\varepsilon} = \frac{\mu_2}{E_2})$.

Pattern of propagation resistance $\sigma_2$ in depth $z$ in the direction of force $P$ Bussinescua formula is displayed [15]:

$$\sigma_2 = K P z^2,$$

where $K$ – dimensionless multiplier.

To determine the effect of the solid reinforcing layer on the nature of the propagation resistance used correction coefficient.

Also (using coefficients) the Bussinescua formulas are corrected with the aim of approximation of the calculated pattern of propagation of resistance in soft soils to real

Deformation of pneumatic tires and soils adequately reflects the three- and two-element rheological models, respectively. Using the scheme of interaction of the elastic wheel with the soil and the selected rheological models of contacting bodies, we find an analytical description of the processes of simultaneous deformation at wheel rolling. For this, the elementary sector of the scheme of interaction (Fig. 2) will be presented in the form of sequentially placed models of pneumatic tires and soil.

![Fig. 2. Interaction of rheological models of tires and soil](image)

Determine what changes occur with the models when rolling the wheel on the ground. If time $t$ deduct from the moment when $\varphi = \varphi_0$ then on the front of the contact $\varphi = \varphi_0 - \alpha t$, – and on the back $\varphi = \varphi_0 + \alpha t$. Then for any $t$ within the angles of contact, the following relationship is valid [15]:

$$\frac{d\varphi}{dt} = \frac{\varphi_0 - \varphi}{\alpha},$$

$$\frac{d\varphi}{dt} = \frac{\varphi_0 + \varphi}{\alpha};$$

where $\alpha l, R_0$ – the sizes are shown in fig. 2, and $R = \rho + l$. Indices 1 with designations indicate that they belong to the tire, and 2 to the ground. The “plus” signs correspond to the front of the contact, and the “minus” is the rear.

The equation of correlation with respect to deformations and their velocities is obtained after the time division of expressions (12) and (13) into a product $H_1 l R_0$, where $H$ – tire profile height $l_0$ and $R_0$ – initial values of sizes $R$ and $l$.

Can be recorded [15]

$$\frac{dR}{dt} = \frac{\Delta R}{l_0}; \quad \frac{dR}{dt} = \frac{\Delta R}{l_0}.$$

Value $\Delta R$ and $\frac{dR}{dt}$ can be found from equation (15), ie.
\[ \Delta R = R_0 \left( 1 - \frac{\cos \phi_0}{\cos(\phi_0 - \omega t)} \right); \]
\[ \frac{dR}{dt} = -\alpha R_0 \sin \phi_0 \cos(\phi_0 - \omega t). \]

After substitution, expression (14) values \( \epsilon_2 \) and \( \dot{\epsilon}_2 \), represented by the calculation of formulas for \( \Delta R \) and \( \frac{dR}{dt} \), we obtain the differential equation of the interaction of the elastic wheel with the ground

\[ \pm \epsilon_1 \left( \mu_1 + \frac{H}{L} \mu_2 \right) + \epsilon_1 \left( E_1 + \frac{H}{L} E_2 \right) \]
\[ = R_0 E_2 \pm \nu E_1 \text{sgn} \omega \frac{R_0}{L_0} E_2 \cos \phi_0 \cos(\phi_0 - \omega t) \]
\[ \pm R_0 \mu_2 \omega \cos \phi_0 \sin(\phi_0 - \omega t). \] (17)

This equation does not have an exact solution, since integrals are not expressed through elementary functions. Numerous methods of integration and grounds for using Taylor series are used for it. These methods do not allow (the second because it is large) to add elementary soil reactions to represent the forces acting on the wheel in the analytical form.

After conducting such an example of theoretical studies, graduates begin to create a laboratory installation and conduct experimental research in laboratory or field conditions.

As a result of scientific research, a pedagogical system was developed, basing on the example of the interaction of the supporting and moving elements of machine-tractor units with soil and on the consistent study of topical production issues, contributes to the improvement of the quality of training and the development of design competencies of the agroengineer.

**Results and discussion.** The developed innovative system of scientific and methodological training of future specialists is based on a planned, cross-cutting, step-by-step growth of knowledge, skills and abilities of future agroengineers. Course designing and master's work provide a qualitative growth in the design competencies of the graduate.

**Conclusion.** The obtained results of the conducted research give grounds to conclude that an effective process of formation of readiness for the project activity of future specialists in agroengineering is possible on the basis of cross-cutting innovative teaching technologies. Coursework and master's work contribute to the development of scientific activities. It is important that they have practical orientation, since this will substantially motivate the students to complete them.

Abstract: 1D simulation has significantly supported the process of developing a diesel ignited high-pressure gas direct injection combustion concept, thus facilitating promising investigations at the SCE. It has been applied to a variety of tasks such as designing the media supply system, pre-optimizing engine operating parameters and developing the safety concept discussed in this paper. Application depends on two simulation models in particular: one validated MCE model and one SCE model enhanced in the course of the concept design phase. Since the MCE model can reliably reproduce the behavior of a full engine with single-stage turbocharging, it played a critical role in determining the boundary conditions for both the 3D-CFD simulation and the simulations with the SCE model. The SCE model, on the other hand, includes all components relevant for the test bed and thus permits both a reliable design of the gas path and the development of a safety concept, which is of remarkable importance for high-pressure gas applications. With regard to the safety concept, this paper presents and discusses the difficulties in detecting injector malfunction and different detection strategies.

Keywords: DIESEL AND GAS FUELED ENGINES, 1D SIMULATION

1. Introduction

The potential for savings in greenhouse gas (GHG) by substituting gases with high methane content (e.g., natural gas) for conventional liquid fossil fuels is considerable due to the comparatively low carbon dioxide emissions, cf. [1, 2]. Applications such as monovalent gas engines and diesel-gas engines that operate on the Otto cycle already exploit this GHG saving potential and are well known for their low emission of both particulates and NO$_x$ as well as for high engine efficiencies, cf. [3, 4].

However, the feeding of a premixed gas-air mixture may result in knocking combustion when gases with low methane contents are used as well as methane slip. Gas-diesel engines based on the diesel cycle directly inject the gaseous fuel into the combustion chamber during the high-pressure phase of the engine cycle. Ignition is triggered by the injection of a small amount of diesel pilot fuel. The resulting mixture-controlled combustion is not prone to knocking and hence, low-quality gases can be used at high compression ratios and therefore high thermal efficiency. Furthermore, these engines have the potential to avoid engine-out methane emissions nearly entirely. Fully flexible gas-diesel engines [4] can be operated either in dual fuel (DF) mode with gaseous fuel as the main energy source or in diesel mode. This redundancy is important in marine applications in particular where fail-safe operation is critical. Application of these engines in liquefied natural gas (LNG) tankers is economically advantageous as the boil-off gas from the LNG storage system is effectively transformed into propulsion energy, thereby increasing overall efficiency, cf. [5, 6].

The development of a new dual fuel gas-diesel engine concept requires the definition and pre-optimization of many parameters in advance. Additionally, the system complexity resulting from having to provide two fuels simultaneously is higher than with monovalent engine concepts. Boundary conditions, knowledge of the thermodynamic states in the combustion chamber during the engine cycle as well as concept specific information on ignition and combustion are all required in the development process. Therefore, the 1D simulation that is part of LDM (LEC Development Methodology) [10] is a good tool that meets the demands of this type of investigation. This paper explains how 1D simulation is applied to a variety of different tasks in the development of a DF gas-diesel engine concept, focusing on a safety strategy for the single-cylinder engine (SCE) test bed.

2. Fuel injection system for gas-diesel engines

One challenge of injecting fuel into gas-diesel engines is that both diesel and gas must be provided at high pressure (HP) levels when they are injected into the combustion chamber at the end of the compression phase. For HP diesel generation, pressure control and media guidance, standard systems can be used. In contrast, HP gas applications for high-speed large engines are less common and the subject of current development activities, cf. [9]. Furthermore, it is particularly challenging to integrate more than one injection valve into the cylinder head. With respect to slow-speed and medium-speed large engines, systems with two or even more fuel injectors are feasible, cf. [5, 7]. In high-speed large engines that feature high power density, however, how the components are packaged within the cylinder head is critical because available space is limited. From investigations of diesel-gas engines with premixed combustion, it is well-known that an off-center positioning of the pilot diesel injector in the cylinder head has disadvantages over the pilot diesel injector being situated in the center, cf. [4]. The off-center ignition of the lean gas-air mixture results in asymmetrical flame propagation, which in turn affects efficiency and combustion stability. Similar disadvantages can also be expected with the gas-diesel concept if the injectors are not arranged centrally. Therefore, advanced injection systems use instead of a multi-injector arrangement one combined gas-diesel injector installed in the center of the cylinder head in which the nozzle is surrounded by the gas nozzle holes, cf. [8]. To obtain the best engine performance possible while complying with stringent emission legislation, the injector has to provide great flexibility in terms of injection timing, multiple injection and injection pressure with both diesel and gas injection. In order to ensure that the injector is always supplied with the required gas pressure and sufficient gas mass flow during the injection process as well, the gas path must be designed accordingly.

3. Advanced high-pressure gas-diesel injector

A recently developed advanced combined HP gas-diesel injector for large high-speed gas-diesel engines meets the demanding requirements described in the previous section. By applying common rail technology, the diesel fuel and the gaseous fuel can be injected flexibly and independently of each other. The
gaseous fuel is injected through three groups of gas nozzle holes; each group has a separate gas needle (one, two or three holes per group). All three groups are positioned symmetrically around the diesel nozzle 120° from each other.

A prototype of a combined gas-diesel injector is available for a detailed investigation and evaluation of the injector concept. The maximum diesel rail pressure of this prototype is limited to 1600 bar in diesel operation mode. In dual fuel operation mode, the diesel rail pressure is limited to 1300 bar and the gas rail pressure is limited to 500 bar. Both gas injection and diesel injection are actuated by two independent valves that are electronically controlled by a modified engine control unit.

4. Media supply of the HP gas-diesel injector

Before the high-speed four-stroke single-cylinder research engine with the diesel-gas injector centrally mounted in the cylinder head is ready for tests, a media supply system has to be developed that is capable of achieving the required gas pressure and sufficient gas mass flow during the injection process in particular. The rough boundary conditions for the design of the media supply are largely specified by the engine application. The detailed engine specifications are given in Table 1.

A well-known common rail technology was used for the diesel supply. In addition, the gas-diesel injector requires a high-pressure gas supply for operation in DF mode. In order to provide the required gas pressures and masses, a new high-pressure gas path in combination with an extended safety concept was developed and implemented at the LEC.

An ion compressor boosts the gas pressure from the low public gas grid level up to 600 bar. The gas pressure in the gas path between the buffer volume and injector is adjusted precisely with finely resolved control valves located downstream of the compressor for fully flexible engine operation. In combination with the latest crank-angle and time-based measurement technology, a special high-pressure NG Coriolis mass flow device monitors all relevant parameters.

Compared to diesel applications with sophisticated flow limitation valves, however, the aggregate state of HP gas poses an increased risk to the engine in the event of injector malfunctions. To identify potential issues that arise during injector malfunction and to develop risk minimization strategies, the gas path shown in Figure 1 was the subject of extensive 1D simulation during the predesign process. In the direction of gas flow, this path consists of a HP buffer volume with a pressure sensor, a safety valve (SV) and another pressure sensor directly upstream of the injector. All these components are highly important for the test bed safety concept and will be discussed in more detail below.

5. Application of 1D simulation to develop a safety concept on the test bed

5.1. Development of 1D simulation models to support the design of a hardware configuration on the test bed

Different 1D simulation models were applied to support the predesign of the gas-diesel combustion concept. Boundary conditions for 3D CFD simulations as well as required engine performance data were calculated with a 1D simulation model of a multicylinder gas-diesel engine (MCE) with one-stage turbocharging. To depict the combustion process with this 1D model, heat release rates (ROHR) were taken from the 3D CFD simulations. To account for the increasing cylinder charge caused by fuel injection during the high-pressure phase of the combustion process, the gas-diesel injector was implemented into the 1D model by including one gas and one diesel injector element in each cylinder.

Since another 1D model of the gas injector alone was required to predict the gas injection rate, a simplified submodel was developed which consists of a spring chamber, needles and a needle chamber, cf. Figure 2 (left). The submodel calibration was based on simulation results provided by the manufacturer of the injector. Figure 2 (right) shows how well the simplified model predicts the target injection at the same boundary conditions.
5.2. Development of a safety concept of a high-pressure gas-diesel injector using 1D simulation

In the development of the reliable safety concept, the pressure conditions within the gas supply path during standard operation from engine start to stop were investigated with this 1D SCE model. All 1D investigations of the gas path used the measurement positions directly upstream of the injector and in the buffer volume. Building on these results, the same model was used to simulate the scenario of a stuck gas needle and its effect on the gas path respectively on the engine at different engine loads while taking the safety valve closing time into account. Finally, successful action strategies were derived. These strategies will be discussed in more detail below in the context of selected scenarios.

5.2.1. Malfunction due to the gas needle sticking during standard engine operation

Figure 4 shows the pressure curves directly upstream of the injector and in the buffer volume of two consecutive working cycles in the event of an injector malfunction during standard engine operation at part load (30%) and full load (100%). Irrespective of the load and position, almost identical pressure curves can be determined in the first working cycle (standard case) with a characteristic pressure fluctuation for the gas injection close to the specified pressure level. Compared to the second working cycle, which represents the scenario of injector malfunction due to the gas needle sticking, the gas pressure drops below the characteristic pressure fluctuation; this is seen most clearly with regard to the position upstream of the injector. In this case, a malfunction can be detected with a threshold value, i.e. if the pressure upstream of the injector falls below this threshold value, the closing process ($\approx 0.1$ s) of the safety valve is triggered immediately and the diesel injection is also switched off in parallel.

5.3. Malfunction due to the gas needle sticking at engine start

Even if an injector malfunction can be detected during standard engine operation, the same approach does not work during engine start. The following section reveals the difficulties in detection by comparing a case in which injector malfunction occurs with a case in which the injector work properly. In this case, the DF engine starting procedure corresponds the one shown in Figure 6. First, the engine is motored up to reference speed (not shown) and the pressure in the gas buffer is raised to the target value of 400 bar before pilot diesel injection occurs (1). In the next cycle, the safety valve is opened (2) and the gas stored in the buffer volume is then able to reach the injector. During this process, the pressure level upstream of the injector increases and finally reaches the same pressure rating as the buffer volume while the gas compressor supplies additional HP gas until the target value of 400 bar is restored throughout the entire gas path (3). Afterwards, the system is ready for the additional gas injection to start the DF mode (4).
Immediately after the safety valve is opened, the gas pressure directly upstream of the injector rises quickly but cannot meet the level of the buffer volume due to the stuck gas needle. Subsequently, the high pressure gradient between the HP gas path and comparatively low-pressure combustion chamber initiates an unlimited gas flow directly into the combustion chamber, which ultimately includes the previously mentioned dangers for the engine.

Since error detection in the gas path via a threshold value worked insufficiently in accordance to the simulation results, further simulations were carried out to identify additional helpful strategies. The indicated cylinder pressure signal was identified as a promising parameter for much faster detection of injector malfunction during both engine start and standard operation. In this gas-diesel concept, air alone is compressed between inlet valve closing (IVC) and start of injection (SOI) in standard operation independent of gas pressure or engine load. As a result, the pressure curve signal can be precalculated by a polytropic state change in independent of gas pressure or engine load. As a result, the pressure curve signal can be precalculated by a polytropic state change in

malfunction during both engine start and standard operation. In this time window and used in a real-time comparison with the measured signal of the indicated pressure sensor, cf. Figure 8. If the gas needle stuck, additional gas would flow into the combustion chamber during this time window and the value of the measured indicated pressure would deviate from the predicted curve without delay. Thanks to this finely resolved monitoring, injector malfunction is detected very quickly and has been successfully used on the test bed in combination with error detection in the gas path via a threshold, which facilitates additional monitoring of malfunctions within the gas supply system.

Abstract: At the present days the great attention is given to a problem of research of hydrodynamics and heat exchange in the pulsating flows. Experimental studies for the flow in smooth channels show that the pulsation of fluids flow significantly affects to the heat transferring and can be accompanied by both reduction and increasing in the intensity of the heat exchanging. This problem has a big practical importance in the study of unstable processes in a various moving and power plants. The results showed that with unsteady fluid’s flow with an alternating pulsations relative to the average velocity in a discretely rough channel is furthering to the intensification of the heat transferring. It is shown that flow pulsations significantly affecting on the heat transferring coefficient, and its average values. This fact opens up the possibility of using such currents to increase the energy efficiency of various technical devices.

KEYWORDS: HEAT TRANSFER ENHANCEMENT, DISCRETE ROUGHNESS, COMPUTER MODELING, NUMERICAL CALCULATION.

1. Introduction
Much attention has been paid to the problem of studying of the effect of pulsating flows on hydrodynamics and heat transferring in recent years. Experimental studies of unsteady flows at the present day showed that such unsteady process can be accompanied by both reduction and increasing in the intensity of the heat exchanging [1].

Known results of experimental and theoretical [2] studies are often solutions for the specific problems and do not allow making broad generalizations about the level of influence of superimposed flow’s pulsations on the intensity of heat transferring. At this moment, there is not enough reliable information about the kinematic structure of the pulsating flow in the channels under the conditions of superimposed nonstationarity.

Based on the reliability of information about the structure of the pulsating flow in the channel, it is possible to estimate the effect of superimposed pulsations on the heat transferring, as well as to identify patterns of changing in flow’s characteristics under considered conditions.

This fact opening up the possibility of using such flows to increase energy efficiency in the studying of unstable processes in various moving and energy equipment.

Thus, obtaining information about the structure of the pulsating turbulent flow and identifying patterns of heat exchanging processes of such flows in discretely rough channels is urgent task for the present time.

The main goal of this work is to use computer simulation and numerical analysis to investigate the effect of periodic flow pulsations on the heat transferring in a channel with discrete roughness in the shape of hemispherical concavities.

2. Prerequisites and means for solving the problem
Analyzing of the existing literature has shown that there are extensive reviews of hydrodynamics and heat transferring studies in smooth and discretely rough channels with a stationary flow of coolant [2-5].

The heat exchange of a hydraulically smooth circular channel with a stationary developed turbulent flow has been studied in detail and well described by the M.A. Mikheev dependence [12] for various regimes of forced fluid flow in a smooth channel.

It is also known that increasing in the intensity of heat exchanging between the coolant and the heat exchange surface is provided, as a rule, with the help of discrete roughness, leading to the partial or complete destruction of the boundary layer, in which concentrated the greatest thermal resistance, as well as significant turbulization of the flow. These effects are achieved by the organization of flow’s separation and attachment areas, an increase in the relative flow velocity near the wall, and generation of the pressure pulsations in the flow and other ways of influencing to the near-wall structure of the flow [6-8].

The experimental and theoretical results of the study of pulsating flows that exist today are mainly obtained only for the boundary layer and the flow in a smooth channel [9,10].

For the successful using of the detachable areas, it is necessary to know the mechanism of their interaction with the main turbulent pulsating flow and the mechanism of the processes in the detachable area itself. These processes are very complex.

At this stage, numerical research methods using the latest advances in the field of boundary layer diagnostics and computerization are the most effective way in the modern theory of heat and mass transferring.

In this work, in order to solve the heat transferring problem in a channel with discrete roughness in the shape of concavities with pulsating fluid motion, 3D modeling software complex CAD/CFD of SolidWorks / Flow Simulation is used.

With using the SolidWorks CAD software calculating and building three-dimensional geometric model of a discretely rough channel.

The numerical solution of the problem is performing in the Flow Simulation software, in which the motion and heat transferring of a fluid is modeling with using the Navier – Stokes equations [11], which describe in unsteady formulations the laws of conservation of mass, momentum and energy of a given medium. In addition, using equations of state of the components of the fluid, as well as the empirical dependences of the viscosity and thermal conductivity of these components of the medium on temperature.

Considering the complexity of the research task, the insufficiency and inconsistency of the existing well-known research results, it is necessary to determine the accuracy and reliability of the results of numerical calculations. For this purposes two main problems were solved:
- carried out series of calculations on the grids with different resolution of the geometric features of the model and non-linearity of the calculated physical parameters field to ensure that there is grid convergence of the solution to the problem and to obtain the final solution of the problem on the optimal (in terms of the accuracy of the mathematical problem solving taking into account computer resources and performance) of the computational grid.
- in a non-stationary problem formulation, perform time discretization for each cell of the computational grid in the computational area from the Kurant condition and determine the allowable maximum time step depending both on the values of physical quantities and the space discretization step in the cell area.
3. Solution of the examined problem

Computer simulation was carried out using the CAD/CFD complex software SolidWorks / Flow Simulation. In the SolidWorks CAD software was constructed calculated three-dimensional model of a circular channel with discrete roughness in the shape of hemispherical recesses (concavities) with a sharp input and output edges arranged in a corridor order.

The internal diameter of the channel is \( D = 0.018 \text{ m} \), the wall thickness is \( t = 0.002 \text{ m} \), the length is \( L = 1.6 \text{ m} \). The relative pitch \( S \) between the axes of the concavities is \( S/h = 10 \) (the \( h \)-radius of the concavities), the concavity setting angle \( \varphi = 120^\circ \). The walls of the channel were modeled as aluminum and heated to a temperature of \( t_{\text{wall}}=105^\circ \text{C} \). At the entrance of the channel supplied working fluid - water, with a temperature \( t = 2^\circ \text{C} \).

In this work using a model of a periodically pulsating internal fluid flow (1) with a sinusoidal type speed pulses (Fig. 1):

\[
V(t) = 0.4 (1 + A \sin (2\pi f t)) \text{ m/s},
\]

(1)

Here \( t \) is time, \( V(t) \) is a flow rate, \( A = 1 \) is an amplitude of the pulsations. The time-averaged flow rate for the all cases are the same and equal \( V_0 = 0.4 \text{ m/s} \).

For the velocity \( V_0 = 0.4 \text{ m/s} \) the average Reynolds number is \( \text{Re}_0 = V_0 D/\nu = 7157 \), where \( \nu = 1.006 \times 10^{-6} \text{ m}^2/\text{s} \) is the kinematic coefficient of water viscosity at \( t_{\text{wall}} = 20^\circ \text{C} \).

With a changing in the average Reynolds number, the average velocities changing accordingly. The instantaneous values of the Reynolds numbers \( \text{Re}_0 \), \( \text{Re}_1 \), \( \text{Re}_2 \) depending on time and for the case (1) are described by the equation

In the calculations, the range of the flow pulsation frequency \( 0 \leq f < 130 \text{ Hz} \) was investigated.

Fig. 1. Flow velocity profile: dashed line - average speed; smooth line - speed, determined by equitation (1).

The results of numerical calculations, generalizing a series of computer experiments, were processed in the dimensionless Reynolds \( \text{Re} \), Strouhal \( \text{Sh} \), and Nu Nusselt criteria:

\[
\text{Re}_0 = V_0 D/\nu, \quad \text{Sh} = f D/V_0, \quad \text{Nu} = \alpha D/\lambda,
\]

(3)

where \( \text{Sh} \) – the dimensionless frequency of flow pulsations, \( \alpha [\text{B/(m²K)}] \) – the heat transfer coefficient, \( \lambda [\text{B/(m K)}] \) – the heat conduction coefficient of the liquid.

4. Results and discussion

The results showed that unlike to the stationary case with a unique dependence \( \text{Nu} = \varphi(\text{Re}_0) \) in a pulsating flow, the instantaneous values of the coefficient \( \text{Nu}(t) = \varphi(\text{Re}_0) \) changing with changing the instantaneous values of the Reynolds numbers \( \text{Re}_0 \) (the \( \text{Re}_0 \) value is determined by equitation (2)). Changes in the instant Reynolds numbers are shown in Fig. 2. In the stationary case with \( V_0 = 0.4 \text{ m/s} \), the Reynolds number is \( \text{Re} = 20000 \). For example, in a pulsating flow at a pulsation frequency of \( f=20\text{Hz} \) (Strouhal number \( \text{Sh} = 0.9 \)) and an average speed of \( V_\text{aver}(t)=0.4 \text{ m/s} \), the average value of the Reynolds numbers increases to \( \text{Re} = 27000 \), as well as has it’s minimum \( \text{Re}=50000 \), and the maximum \( \text{Re}=47000 \text{ value} \).

As a result for the each value of \( \text{Re}_0 \) corresponds to its own \( \text{Nu} \) value and is limited to its minimum \( \text{Nu}_{\text{min}} \) and \( \text{Nu}_{\text{max}} \) maximum values. This effect is due to the periodic change in the Reynolds number and the inertia of the processes during unsteady fluid flow in the channel.

Fig. 2. Changing of the instant Reynolds numbers. Line 1 - stationary flow \( V_0 = 0.4 \text{ m/s} \); line 2 - pulsating flow \( f = 20\text{Hz} \) (\( \text{Sh} = 0.9 \)) \( V_\text{aver}(t)=0.4 \text{ (m/s)} \).

For the dependence \( \text{Nu} = \varphi (\text{Sh}) \) can be selected conditionally three characteristic areas (Fig. 3.). In the first zone, \( 0 < \text{Sh} < 2 \), the frequency of the flow velocity pulsations leads to the increasing in the average values of the Nusselt \( \text{Nu}_{\text{aver}} \) numbers in relation to \( \text{Nu}_0 \) for the stationary regime of the fluid flow.

Fig. 3. The dependence of the Nusselt number on the dimensionless frequency of flow pulsations \( \text{Nu} = \varphi (\text{Sh}) \).
In the second area 2 <Sh <4.3, the average values of the Nu\text{aver} numbers become lower relative to Nu_0 by about 10-15%. In Fig. 2 can be noted that when the dimensionless Strouhal number Sh ≈ 2 is reached (zone 2), the heat exchanging getting worse. In the third zone, 4.3 <Sh <6, the average Nu\text{aver} value in relation to Nu_0 stabilizes and the value of Nu remains almost unchanged and the flow pulsations have almost no effect on the heat transferring.

Fig. 4. shows visualization of a flow in a channel with a discrete roughness (longitudinal section), in the case of stationary flow of a fluid at average speed at the entrance to the channel V_{inlet} = 0.4 m/s. The flow under consideration can be conditionally divided into the three areas: I – the outer boundary layer, II – the mixing region, and III – the return flow.

The flow picture can be presented as follows. The incident flow V at the exit from the concavity is turbulent, mixed with the medium in the concavity, and carries particles of the liquid from the mixing zone to the main flow. At the same time at an enviror of the outlet edge the flow is splitting. One part of the flow (laminar sublayer) moves along the straight wall of the channel, the other part goes around the surface of the concavity and when it reaches the input edge of the concavity (inlet edge) it breaks down and forming a vortex.

The Fig. 5. shows the temperature distribution on the transverse axis of the channel AB (r (mm)); the steady flow is V_{inlet} = 0.4 m/s line 1 – is a smooth channel and line 2 – is a discretely rough channel.

In comparing with the stationary motion in the pulsating mode, the flow patterns changing at time t(s).
begins to move closer to the channel axis, where it merges with the main fluid flow, and thus forms a vortex zone III. The center of the vortex is located on the axis AB and at a distance approximately equal to half the radius of the smooth part of the channel.

![Diagram of flow](image)

**Fig.8. The flow around the pulsating flow $V_{min}(t)$ (m/s) concavity in the channel (longitudinal section) $f = 20$Hz ($Sh = 0.9$).**

So it can be assumed that the presence of vortex structures and return flow zones on the heat exchanging surface leads to the destruction of the boundary layer and, accordingly, intensifies the heat exchange processes. And the occurrence of such disturbing factors in the flow significantly affects both the hydrodynamics of the flow and the heat transferring.

5. Conclusion.

In this work was established that nonstationary processes can be accompanied by both an increase and a decrease in the intensity of heat transferring.

It is shown that this is due to the presence of vortex structures and backflow zones on the heat exchanging surface. Which lead to the destruction of the boundary layer and, as a consequence, lead to the intensification of heat exchanging processes.

It is revealed that the periodic pulsations of the flow velocity of fluid in discretely rough channels have a significant effect on the heat transferring coefficient $Nu$.

Unlike to the stationary case, in a pulsating flow, the instantaneous values of the coefficient $Nu$ changing as the instantaneous values of the Reynolds numbers $Re_t$.

The presence of the three characteristic zones of dependence of the Nusselt number $Nu$ on the dimensionless Strouhal number $Sh$ $Nu = \varphi (Sh)$ is established. In the first zone ($0 < Sh < 2$), the pulsations of the fluid flow in the channels improve the average intensity of the heat exchange. In the second zone ($2 < Sh < 4.3$), the average intensity of the heat exchange is accompanied by a decreasing.

In the third zone ($4.3 < Sh < 6$), the flow pulsations have practically no effect on the average value of the heat exchanging, and the average value of the Nusselt number becomes approximately the same as for the stationary flow.

MULTISCALE MODELING OF SHORT FIBRE REINFORCED COMPOSITES AND IT’S RELATIONSHIP TO MODAL ANALYSIS OF MACHINERY PARTS

IDIADA CZ a. s., the Czech Republic
jarmil.vlach@idiada.cz

Abstract: Although molding of thermoplastics is very productive method of machinery manufacturing, pure plastics are almost not used in so much quantity. Particle reinforced composites are more popular, because presence of solid inclusions reduces volume of organic matrix and usually improve strength and stiffness. Final properties are strongly influenced by manufacturing process which affects inner material structure. In composites where fibers are continuous in one direction or placed in layers, i.e. the fibers do not end inside the composite and it’s length is close to the dimension of machinery parts, elastic [1] [2] and thermal properties [7] can be predicted quite easily by Halpin-Tsai equations or derived simplified methods [2] with high accuracy. This paper is focused on prediction of density and material stiffness of composites, which are reinforced with very short glass fibers in thermoplastic matrix. In the first part we define the field of problem. Then we present simplified analytical calculus in compare to finite element method. We focus on ABAQUS 2018 and its features, which can be used for solving those problems. Estimation approaches such as representative volume element method and mean field homogenization are also studied. After this presented methods are confronted with selected material datasheet of Ultramid® A3 and Zytel® 70G35HSLRA4 [12] composite material. The effect of fiber randomization on material stiffness is introduced [4]. At the end of thesis we use previously calculated material data for modal analysis of real parts which are made from molded thermoplastic with short glass as well.

Keywords: MODAL ANALYSIS, ELASTIC PROPERTIES, SHORT FIBER, THERMOPLASTIC, COMPOSITE

1. Introduction

In the case of large thin-walled and low-ragged composite components, which are reinforced with long fibers, the volume representation and orientation of the reinforcement are constant. Prior to injection of the binder phase, the reinforcement is generally positioned and fixed in the mold such that during the production process to transfer the matrix was prevented from moving it. As the reinforcement position is known in advance, the assumed properties of actual products usually coincide well with the calculations and correspond to our expectations. The problem of molding short fiber reinforced composites stands on the opposite side of accuracy interval, because the order of the system is much lower than in case of long fiber composites.

In terms of access to the development process, it would be optimal if separate injection simulations were made for each type of material. In our article, we deal with the possibility that only one simulation is performed and only small variations in elastic material parameters would occur. We assume that fiber volume changes in percentage order will not lead to fundamentally different distribution and orientation results, while material parameters may have a more significant effect.

In this work, we have considered the primary objective of verifying the accuracy of material properties prediction in connection with injection simulation, followed by experimental modal analysis, because the problems of linear dynamics and elastic wave propagation are closely related.

2. Injection simulation

The simulation results are sensitive to the quality of the FE mesh and the type of used element. In this case, we consider the analyses contains output mesh of the injection simulation from Moldflow software. Because it is a flow problem where the mesh is stable in the space (it does not deform), but the mass moves inside, it is a description in Lagrange coordinates. The simulation provides sufficient information on the distribution, concentration and orientation of the material in the individual elements.

This type of mesh is often not suitable for distortion and stress analysis when individual nodes move and structure deforms, although in case of small strains, the model mesh can give satisfying results. However if there are large deformations or strains in the interval of plasticity, such a model can no longer be used, because the intermediate results will no longer meet the convergence criteria or give not good response to real problems. Therefore, the next step of work usually is to create a model mesh that would meet the least requirements. The flow model must then meet the solvency criteria and the possibility of transmitting some information so that the result is not affected.

3. Multiscale modelling of material properties

Each computational material model of composite material can be divided in few basic parts. The first section at the macroscopic level is usually a body or a machine component, consisting of a discretized network of elements representing a particular region. These are material properties that correspond to the microstructure level scale of the unit characteristic. It is important to mention that each of presented predictive theories reminded bellow works with another type of this elementary cell and therefore the results of the material characteristics differ from one another.

![Fig. 1 Schema of direct and indirect analysis procedure](image-url)
4. Short fiber reinforced composite materials

Parameters that have a key effect on material characteristics are fiber length ($l_f$), fiber diameter ($d_f$), shape and volumetric fraction of the reinforcements ($\phi$). The most important describing parameter is shape factor ($\xi$) [1]. Physical parameters are given by material characteristics of components (Table 1). Since short fibers produced in a special machine are shortened by cutting or milling of long fibers and the length of each fiber is essentially unique, we must work with it as a statistical variable. For this instance, we consider the significant fiber length 120 $\mu m \pm 19$ $\mu m$ at 95% probability level. Fiber diameter is considered as constant value which is 10 $\mu m$. The relevant prediction of mechanical properties is therefore a rather complicated process where each of the variables we only predict with a certain degree of accuracy.

In this work we mainly deal with elastic properties of binary composites with polyamide matrix and reinforcement from E-glass. We took the properties of the matrix from the material sheet Ultramid A3W [8] and confronted with literature [2], glass properties were taken from [2] a [3]. In all the calculations, we consider the matrix as dry or low in moisture. We view both components as homogeneous isotropic materials.

For prediction of the composite material properties [9] [12] three basic methods were used. The traditional analytic method (AM) represents Halpin-Tsai equations (HT). The second was representative volume element method (RVE), which was applied on three basic cells with cylindrical and prolate reinforcement. It shows Fig. 4, while the effect of connected and disconnected front boundary of cylinder was studied [2]. The last approach was mean field homogenization (MFH), when various formulations reminded in Table 2 were used and the only ellipsoid-prolate inclusion was considered. In case of (HT), the properties were directly calculated from one element model following formulas (1), (2) and (3). When we consider material as separated entities (RVE) formula (4) should be used.

\[
E_{ij} = \frac{\sigma_{ij}}{\epsilon_{ij}}; \quad E_{ij} = \frac{\tau_{ij}}{\gamma_{ij}} \quad E_{ij} = \frac{\phi_j}{\phi_i} \quad E_{ij} = \frac{\xi_i}{\xi_j}

**Fig. 3 Basic experiments applied on MFH and RVE models**
Experimental modal analysis is the method which allows to obtain mathematical model of the vibration properties and behaviour of the structure by experimental means. The modal parameters are established by measuring and processing of frequency response function $H(\omega)$, given as

$$H(\omega) = \frac{H(\omega)}{F(\omega)}$$

where $F(\omega)$ is excitation and $X(\omega)$ is response of the system, both in frequency domain. In our case we tested parts freely suspended in the center on rubber bands with low stiffness. For each part the experiments were done at 11 different positions of actuator while sensor position was fixed. Results were analyzed following literature [13].

---

In second variant the successful (MFH) Mori-Tanaka was applied on user created mesh, when FE model was simplified in way that 9 elements thru thickness were reduced on 3 and the same distribution of material given by orientation tensor which was mapped on was used.

As third variant we considered the initially calculated distribution of material from Moldflow valid again and just mapped on user created mesh again, but this time material card was generated by using (HT) method.

### 6. Modal analysis of real parts

#### 6.1 Simulation

Task of this section was to verify the previously studied assumptions for real products, which shows Fig. 7 a), b). Present product, which consists of a two-piece assembly, was made by injection technology of short-fiber reinforced thermoplastic material [12]. The aim was to compare the results of modal analyses with different model mesh settings and engineering elastic constants. In this case, calculations have been performed in ways that were recognized as effective. In total, modal analysis of individual components were performed, then results were compared with the experimentally determined values. Temperature of surroundings was considered 23°C.
8. Conclusion

Most of the methods did a well of predicting longitudinal modulus. The worst results are provided by MFH Prolate Inversed Mori-Tanaka method and we think material isotropic. Overall result with deviation from -38% for Zytel and 46,8% for Ultramid is unacceptable. Best deviation has been achieved using Prolate Mori-Tanaka. Halpin-Tsai equations reaches the boundary of dev. -5 and -8% for both materials. This can be considered also as sufficient. Deviance of other properties was found lower or same orders but not published.

![Fig. 10 Deviance of E, modulus from datasheet](image)

![Fig. 11 Deviance of modal frequency results to experimental, Cover](image)

![Fig. 12 Deviance of modal frequency results to experimental, Housing](image)

Although the material settings of initial components were the same, modal frequency determined from original Moldflow model is influenced by largest error. The total average deviance from experimental is 25,2% (housing) and 27,3% (cover). In case of cover part the smallest deviance is obtained from model with mean field homogenization where Mori-Tanaka formulation was applied and which property was also mapped on user mesh. Smallest deviance from experimental was 8,8%. It was proved that successful calibration of material properties and proper choice of prediction method in a key way influence results. Modal frequencies and modal shapes match with experiment quite well although the prediction deviance of natural frequencies is higher then material. It is caused by natural distribution of fibers which is statistical value and low order of the system.

IDENTIFICATION OF THE MINOR CHEMICAL ELEMENTS IN THE EXHAUST EMISSIONS FROM DIESEL ENGINE VEHICLES

Dr. Richard Viskup, M.Sc. Christoph Wolf, Prof. Dr. Werner Baumgartner
Institute of Biomedical Mechatronics – Johannes Kepler University Linz
Altenberger str. 69, 4040 Linz, Austria
Richard.Viskup@jku.at

Abstract: In this research we investigate the minor chemical elements contain in the particulate matter (PM) exhaust emissions, generated from in - use light duty Diesel combustion engine vehicles. For this purpose we apply high resolution optical emission spectroscopy technique, for precise spectrochemical analysis of Diesel particulate matter (DPM). By means of Laser Induced Breakdown Spectroscopy analytical method we analyse PM from different on road Diesel engine vehicles. DPM were obtained from miscellaneous in-use Diesel engine passenger vehicles of diverse types and models from major brand car producers in Europe.

Keywords: BLACK CARBON, DIESEL ENGINE, DIESEL EMISSIONS, PARTICULATE MATTER, SOOT, DIESEL VEHICLES

1. Introduction

The existing emission standards like Euro, Tier, or LEV, for light-duty Diesel engine vehicles specify the maximum allowable emissions of hydrocarbons, carbon monoxide, nitrogen oxides and particulate matter (PM). PM is measured as the total number of all generated particles from Diesel exhaust. On another hand, there are no specific emission standards for additional compounds or chemical elements contained in the exhaust emissions i.e. in exhaust vapour, in Diesel particulate matter (DPM), in particulate matter (PM), in black carbon / carbon black (BC/CB), or in the soot formed by the Diesel combustion engine. Even though, the chemical elements additional to carbonous particles, present a large fraction of the total DPM or soot emission contents.

Generally, exhaust emissions from Diesel engine can form a very complex mixture of gases, vapour and particles consisting of countless elements and compounds. Gaseous compounds of Diesel emission include carbon dioxide, oxygen, nitrogen, water vapour, carbon monoxide, nitrogen compounds, sulphur compounds, and numerous low molecular weight compounds [1]. The vapour phase contains larger molecular weight compounds, located in unburned tailpipe emissions. The Diesel exhaust particles are agglomerates of many primary spherical particles that differ in size [2], composition [3] and solubility [4]. The particles in Diesel exhaust emission consist of particulate matter - Diesel particulate matter. This is further classified, depending on the size of particles to: particulates of an aerodynamic diameter of less than 10 μm, fine particles of diameters below 2,5 μm, ultra fine particles - below 0,1 μm and nanoparticles - characterised by diameters less than 50 nm. DPM is composed of elemental carbon in core and adsorbed compound. The elemental carbon core has a high specific surface area and serves as a nucleus for condensation of compounds with good adsorption properties mainly from the unburned or incompletely burned Diesel, particles or from crankcase oil volatilized metallic nano-particles from the cylinder walls.

The aim of this research is to investigate the minor chemical elements contained in the particulate matter exhaust emissions, generated from standard in - use light duty Diesel combustion engine vehicles. For this purpose we apply high resolution optical emission spectroscopy technique for precise spectrochemical analysis of DPM. By means of Laser Induced Breakdown Spectroscopy analytical method we analyse PM from different on road Diesel engine vehicles. DPM were obtained from miscellaneous in-use Diesel engine passenger vehicles of diverse types and models from major brand car producers in Europe.

2.Methodology

In Laser Induced Breakdown Spectroscopy a high power laser radiation, with nanosecond or shorter pulse duration, is interacting with the investigating material [16]. This short light – matter interaction generates a plasma, of which the optical emission spectrum is collected by the optical spectrometer and then further processed by computer. From LIBS spectra, the elemental chemical composition of the examined sample can be obtained. The qualitative spectral information can be further calibrated, to obtain quantitative results. The LIBS technique provides very sensitive and rapid analytical measurements, without sample pre-treatment, in the range of ppm levels [17], almost instantaneously. This advantage pushes the LIBS technique forward in many new research areas and makes it also attractive for industrial applications [18].

The LIBS technique can almost instantly measure the minor compounds of DPM and provide the qualitative results about the chemical composition. The fingerprints of minor chemical elements in PM exhaust emissions are related to different processes. These are: fuel quality, fuel composition, additives, performance of combustion, catalytic reaction, particulate filtering technique, or wearing of the Diesel engine.

3. Experimental setup

3.1 Experimental LIBS setup

The experimental setup for LIBS measurement, consists of high intensity pulsed laser system, experimental chamber, collection optics and with high precision optical spectrometer. Laser beam is generated by focusing of laser radiation into the focusing lens. Plasma is generated by focusing of laser radiation into the material. Schema of LIBS experimental set-up is shown in Fig. 1.

![Fig. 1 Layout of LIBS experimental setup.](image)

For laser induced plasma we have used solid state Nd:YAG laser from Quantel. The laser has 8.5 ns pulse duration, and fundamental laser wavelength operating at 1064 nm in invisible
infrared spectrum. For the measurements we have used the laser energy of 300μJ per single pulse. Due to the large variations of different DPM samples, we apply higher laser energy, to enhance the plasma emission and ensure the gain in overall optical signal for all spectra lines and samples. The laser radiation has been focused with 10 cm focusing lens into the plane solid target surface to create plasma. Optical emission from plasma has been collected perpendicularly via optical telescope into the high resolution Echelle spectrograph model Arayelle Butterfly from LTB Berlin equipped with ICCD detector. Spectrometer consists of two separate spectrographs, one part for UV range from 190 nm to 440 nm and the second part for VIS optical spectrum in range 440 nm to 800 nm. Spectral resolution capability is from 3 - 7 pm for VUV part and 4 - 8 pm for VIS part, thus providing spectral information of a broad spectral range with high resolution and variability. The delay time 1μs and gate width 2 μs after the trigger signal has been used. The LIBS emission has been recorded in open air atmosphere under a atmospheric pressure at room temperature.

3.2 Particulate Matter collection and sample preparation

Sixty-seven different samples from in-use Diesel engine passenger vehicles of major brand car producers in Europe have been analysed by LIBS. Vehicles selected for the DPM sample collection were from our daily life environment, as anyone is using to drive to work, etc, no special driving test cycles vehicles or collection were from our daily life environment, as anyone is using.

3.2 Particulate Matter collection and sample preparation

Sixty-seven different samples from in-use Diesel engine passenger vehicles of major brand car producers in Europe have been analysed by LIBS. Vehicles selected for the DPM sample collection were from our daily life environment, as anyone is using to drive to work, etc, no special driving test cycles vehicles or engines were used. Diesel Particulate Matter has been collected and extracted from the tail pipe at the end of the exhaust manifold, after the Diesel Particulate Filter (DPF), if it was applied. Selections of the vehicles were performed randomly and no company was given preference. The collected DPM from Diesel engine vehicles exhaust has been mechanically pressed into the small pellets with 6mm diameter and with flat disc shape.

4. Results and discussion

4.1 Identification of the major elements in the DPM

Obtained signal from Laser Induced Breakdown Spectroscopy measurements of Diesel Particulate Matter from three selected samples, are shown in the Fig. 2. The strong optical emission is characterise from Carbon, Iron, Magnesium, Aluminium, Chromium, Zinc, Sodium and Calcium. These elements were previously identified in PM as major components of Diesel Particulate Matter [19].

LIBS spectra generated from particulate matter collected from in-used Diesel engine light-duty vehicles exhibits a characteristic spikes - optical emissions lines with distinct of atomic, ionic and molecular origin included in the signal.

4.2 Identification of the minor elements in the DPM

To identify the minor elements of DPM the state-of-the-art laboratory Laser induced breakdown spectroscopy setup has been used to obtain high resolution optical emission spectra image. The qualitative LIBS results of these measurements are shown in Fig. 3(a-f). Obtained signal from minor chemical elements are characterised by strong optical emissions from: a) Silicon, b) Nickel, c) Titan, d) Potassium, e) Strontium and f) Molybdenum.

Minor elements of DPM matrices:

Silicon spectral line: atomic emission from Si I @ 288.15nm is shown in the Fig. 3a. In this figure the raw spectral signal from LIBS measurements of sixty-seven different samples of Diesel particulate matter are shown. From this spectroscopical results one can observe that the Silicon signal, mainly peak shape, peak intensity and peak width at FWHM varies for each DPM sample. The strength of the LIBS signal of particular atomic or ionic line is basically proportional to the concentration of the analyte in studied sample. Therefore for detail comparison we numerically calculated the integral values of each signal peak to obtain qualitative information about chemical composition of Diesel particulate matter. The results from these calculations are shown in Fig. 4a. Here one can easily compare the variations of Silicon signal / concentrations (a.u.) within diverse DPM matrices. However for detail quantitative analytical characterisation of Si in DPM, the calibration of LIBS signal would be desirable. To compare; very high content of Si is in the sample # 51, 31, 25, 55. From LIBS analytical measurements and numerical calculations we can conclude that Silicon is minor element and it has been measured in 63 from 67 different DPM samples.

Nickel spectral line: in Fig. 3b the comparisons of ionic emission from Nickel, spectra line Ni II at 221.64nm is shown. One can see, that this signal is quite strong. The calculation of signal integral values is in Fig. 4(b). Samples with high content of Nickel are #12, 4, 34, 5, 20. Nickel in DPM is present as minor element in the 43 samples.

Titan spectral line: is compared in Figure 3c, where the ionic spectra lines Ti II at 334.94nm is shown. From the numerical calculation in Fig. 4c one can see, that optical emission from this element is present in 32 DPM matrices. High content of Titan is present in sample #51, 55 and 59.

Potassium spectral line: is shown in Fig. 3d, as atomic line K I at 766.68nm in infrared spectral range. High content has been measured in sample #51, 4, 26, 28, 25 and 8. The comparison of integral spectral peak calculated values are shown in Fig. 4d. Potassium is present in 50 different samples.

Strontium spectral line: the raw peak signal from sixty-seven different DPM samples is shown in Fig. 3e. The Sr ionic line Sr II at 407.77nm, is present in visible spectral range. From numerical calculation in Fig. 4e the Strontium as minor element has been measured in 35 different DPM samples. Strong signal from Sr is in sample #4 and 51.

Molybdenum spectral line: atomic emission Mo I @ 313.25nm is shown in Fig. 3f. From the figure, higher content of molybdenum is in two samples, #12 and 59. Molybdenum as minor element has been measured in 17 different DPM. The comparison of integral values are shown in Fig. 4f.

In Table 1 are summarised measured analytes, the spectral atomic or ionic lines used for analytical LIBS measurements and number of samples where the minor element has been successfully detected.
Fig. 3 Optical emissions spectrum from: a) Silicon, b) Nickel, c) Titan, d) Potassium, e) Strontium and f) Molybdenum signal, measured by high resolution LIBS technique from Diesel particulate matter collected from in-use passenger Diesel engine vehicles.

Fig. 4 Comparison of calculated integral values from optical emissions spectrum of a) Silicon, b) Nickel, c) Titan, d) Potassium, e) Strontium and f) Molybdenum minor chemical elements in Diesel Particulate Matter.
5. Conclusions

In this paper, we have investigated the minor chemical elements present in Diesel Particulate Matter. The DPM have been collected from sixty - seven different in-use Diesel engine passenger vehicles. Selections of Diesel passenger vehicles have been performed randomly, from daily life environment and from major brand car producers in Europe. Particulate matter have been analysed spectrochemically by means of a high resolution laser induced breakdown spectroscopy (LIBS) technique. The qualitative analytical results have shown the presence of minor chemical elements: Silicon, Nickel, Titan, Potassium, Strontium and Molybdenum in Diesel particulate matter. These elements were measured by LIBS as strong spectral lines of atomic and ionic emission in laser induced plasma. The spectral LIBS signal from each minor element was further numerically processed. The integral values of individual signal lines have been calculated to obtain qualitative comparison of individual minor elements in different Diesel particulate matter matrices. From analytical measurements and numerical calculations we can conclude that Silicon as minor element has been detected in 63 from 67 DPM samples. Nickel and numerical calculations we can conclude that Silicon as minor element have been detected in 17 DPM samples from different in-use Diesel engine passenger vehicles. Measured minor elements Si, Ni, Ti, K, Sr, Mo together with major elements C, Fe, Mg, Al, Cr, Zn, Na and Ca are forming important part of Diesel particulate matter composition. All these elements are altogether contributing to overall exhaust emissions from Diesel engine passenger vehicles.

We can conclude that the LIBS technique can almost instantly measure the major and minor compounds of DPM to provide qualitative information about the chemical composition. The presence of these chemical elements in PM exhaust emissions are related to different processes in Diesel combustion engine.

However in the future, a detail quantitative analytical characterisation of minor elements, together with calibration procedure would be necessary to obtain. This would help to understand the minor element concentrations in Diesel particulate matter.

FINDING THE OPTIMAL COMPENSATOR CONTROL MATRIX IN THE LONGITUDINAL CHANEL FOR DEVELOPED MUAV

M.Sc. Biliderov S. PhD.¹
Faculty of Aviation, Dolna Mitropolia – National Military University, Veliko Turnovo, Bulgaria ¹

biliderow_ss@yahoo.com

Abstract: The presented report examines the isolated longitudinal movement of a mini unmanned air vehicle type flying wing. The overall dimensions and the mass characteristics are taken from the developed MUAV. These features are introduced into the software environment of the virtual aerodynamic tunnel. The resulting mathematical model is statically balanced in the isolated longitudinal movement and the openloop system has been stability examined. The received state matrix is introduced into the state space model of the isolation longitudinal movement and the system is tested for stability and controlability. A matrix of the compensator is synthesized, and its optimal coefficients are found by two methods.

Keywords: MUAVs, VIRTUAL WIND TUNNEL, OPTIMAL COMPENSATOR CONTROL MATRIX

1. Introduction

The safety is an important factor in the sustainable development of the society [9]. The modern world has become more and more insecure. This uncertainty leads to crises, whose analysis, risk factors and characteristics become more and more diverse [4]. It is particularly convenient to use aviation in operations in response to large-scale disasters [3].

In this dynamic security environment, unmanned aerial vehicles (UAVs) are increasingly finding their place and application. The manufacturers of UAVs strive to make them more efficient and reliable. For this purpose, a number of methods for forecasting the technical condition of the aviation equipment installed on board are used [5], [6].

In addition to the aviation equipment, UAVs efficiency and reliability depend on the design methods of their construction [13], the choice of a geometric schem with the suitable aerodynamic quality [11] and the studies that are made in this direction with real [14] and virtual [16] aerodynamic tunnels. The use of software products to study the aerodynamic characteristics of the airfoils and wings is growing. For this purpose an appropriate free product is XFLR5 [17].

Computer systems and software products shorten the time when developing the mathematical models of the UAVs movement [7], [18] and through them the synthesis of suitable autopilots and automatic control systems are made. Especially important here are real experiments as well as technical means and algorithms for flight information processing [2]. The data from these experiments are obtained from the on-board equipment and the ground control station [1] using the sensors included therein [12].

The main purpose of this study is with the free software product XFLR5 in its virtual aerodynamic tunnel environment to be made a research of the developed mini UAV (MUAV) to produce the state space matrix for isolated longitudinal motion. After that, a mathematical model of the motion in the longitudinal channel to be developed. Then, an appropriate control by optimizing the compensation control matrix to be synthesize.

2. Testing MUAV in a XFLR5 wind tunnel

A flying wing aircraft type was developed, from which the shape of the airfoils and the overall dimensions of the planer were taken. The airfoils from which the wing of the MUAV is made are drawn in the XFLR5 software airfoil section environment. After that, the airfoil aerodynamic characteristics have been investigated. Using the downloaded dimensions of the MUAV and the previously drawn aviation airfoils the whole sailplane was drawn in the aircraft section environment of the same software product.

On the drawing MUAV, the locations of the main parts, such as the battery, the autopilot, the steering gear, etc., have been defined, and their mass characteristics are set. Based on mass features, the XFLR5 software calculates the inertia moments and the center of gravity of the MUAV.

For the purpose of the study, only the longitudinal channel of the isolated longitudinal movement of the MUAV is considered. Range of speeds and angles of attack were set and the aerodynamic characteristics of the MUAV were taken. The experimental setting of the study is shown in Figure 1.

Fig. 1 Testing MUAV in a XFLR5 wind tunnel environment.

A static balancing of the MUAV has been performed by deviating the end portions of the airfoils where are the steering wheels of the real aircraft. After the static balancing, the movement
of the MUAV in the isolated longitudinal direction of the flight was investigated at the specified frequency and the amplitude of the disturbances.

In the event of atmospheric disturbances in the vertical plane, a longitudinally-oriented horizontal flight of the MUAV is performed by two types of movements: short periodic and long periodic [10]. The short period movement in the XFLR5 environment is shown in Figure 2. It is high frequency a vertical movement at the same time with the angular velocity of the pitch. This movement is well damped, but it is difficult for the operator of MUAVs because it is invisible.

The long-period movement is described by a figure called the fugoid and is shown in Figure 3. In the execution of this movement, the lift force is changed by converting the kinetic energy into potential and vice versa when diving and climbing the MUAV.

The two movements in the isolated longitudinal channel (long and short periodical) are fluctuating in nature. The capabilities of the XFLR5 software product include depicting the location of roots of the characteristic equation for short-period and long-period motion.

The rootlocus position in the complex plane is shown in Figure 4. In this figure, the roots of the short-period movement are far at the left, while the long-periodic ones are close to the imaginary axis.

The characteristic equation is obtained from the state space matrix of the longitudinal isolated movement [15], composed by expression (1):

$$ A = \begin{bmatrix} X_0 & X_w & 0 & -g \\ Z_w & Z_w & u_0 & 0 \\ M_z + M_u Z_0 & M_u + M_u Z_w & M_z + M_u u_0 & 0 \\ 0 & 0 & 1 & 0 \end{bmatrix} $$

The numeric expression values (1) for the longitudinal state matrix found in the XFLR5 software product are shown in (2):

$$ A = \begin{bmatrix} -0.0222984 & 0.00822439 & 0 & -9.81 \\ -0.619111 & -30.6397 & 26.6356 & 0 \\ 6.70861e-6 & -79.5329 & -33.6149 & 0 \\ 0 & 0 & 1 & 0 \end{bmatrix} $$

When the MUAV is subjected to disturbance, it has a physically tends to respond to different flight modes. From a mathematical point of view, these flight modes are called their own (natural) modes and are described by:
1. eigenvalues – describing the flight mode frequency and its damping;
2. eigenvectors – setting the shape of the figure in the described movement reaction.

The numerical values of the eigenvalues and the eigenvectors of this particular isolated longitudinal motion found by XFLR5 are shown in Table 1.

### 3. Optimizing the longitudinal channel compensator control matrix

By the eigenvalues and the eigenvectors of the state matrix, it is established whether the MUAV is resistant to the isolated longitudinal movement. The study is drowned when all states in this movement are observable.

Checking for observability and controllability is done in the MATLAB environment. This is the first thing that needs to be done when designing the system using the space space method. For the states of the system to be fully observable and controllable, the rank of the matrices of observation and control must be equal to the number of independent rows (columns) of the state matrix. The result of the MATLAB environment is shown in (3):

Controllability = 4; Observability = 4

which means that the system is observable and controllable.

The single step function reaction of the open system is shown in Figure 5.
Figure 5 shows that the openloop system cannot reach the desired state vector value. It is necessary to close the system with feedback, so that when the system is entered in the desired state, the system can reach it. Figure 6 shows a developed MATLAB-Simulink model of the closedloop system.

Figure 6 Closedloop system with compensator matrix $K$ equal to one. Initially, the values in the compensation matrix are set to ones. The reaction of the closedloop system of the desired state is shown in Figure 7. It is necessary to find such values in the compensator matrix to control the MUAV in the isolated longitudinal movement so as to reach the desired values of the state space.

In order to find the optimal values in the compensator matrix, a linear-quadratic regulator (LQR) is used to build an LQR-based compensator $K$.

The idea is to minimize the function of the losses $J$ in (3) by optimally selecting the weight matrices $Q$ and $R$ [8].

The state is controlling by error (4) where $x_d$ is the desired value. The synthesized model with LQR compensator $K$ is shown in Figure 8, and in Figure 9 is the results of its operation.

Another method that is convenient to use when setting the compensator coefficients is the MATLAB-Simulink-Control system Tuner option. When entering the compensator coefficients from the model in Figure 6 and determining the input and output signals in the environment of the Control system Tuner, it is necessary to select the aim of the system setting.

In this case, single step response response is selected in the channels of the horizontal velocity and trajectory angle. The pre-set reaction of the model in Figure 6 is shown in Figure 10.

After performing the automatic adjustment of the coefficients of the compensator for the system reaction response in the control channels, the results of Figure 11 are obtained.
4. Conclusions and results

1. The longitudinal channel of the developed MUAV in its isolated longitudinal motion was investigated.

2. The responses of the openloop and closedloop systems of a single step signal and the desired state are compared.

3. Two methods are used to find compensator coefficients - LQR and auto-tuning.

4. The results of the two using methods are similar.

APPROACH OF CALCULATING THE AUTOMOTIVE GASOLINE INJECTOR ELECTROMAGNETIC PARAMETERS

Assoc.Prof. M.Sc. Bozhkov S. PhD.
Department of Transport Equipment, Todor Kableshkov University of Transport
Geo Milev str. 158, 1574 Sofia, Bulgaria
stbozhkov@vtu.bg

Abstract: The electromagnetic fuel injectors automotive are the gasoline injection systems main elements. The injectors perform the gasoline injection and its time of open condition, i.e injection duration determines the fuel quantity per working cycle [1]. The injectors are activated by solenoid and inject the gasoline in the engine manifold at the system pressure [2]. The gasoline injectors ensure precise fuel metering according to engine work state. The injectors are controlled by control signals, whose parameters are defined by the engine management system. The control devices are power transistors (drivers) in the electronic control unit (ECU). The injectors synchronizing and speed activating has a special significance and influence upon the increasing of the power and efficiency and the decreasing of the harmful emissions of the automotive engines. The synchronization of the electromagnetic gasoline injectors is connected by one hand of the injection according engine work order and by the other – with equal fuel injection duration and injection quantity. Meanwhile the injectors work at such conditions, which imposed constant compensation and adaptation activities by the ECU. This circumstance is connected with requirements of speed activating, which is measured by indicators, such as minimal electromagnetic activating force and minimal opening and closing time. This paper is considered the method of calculating the electromagnetic parameters of the automotive electromagnetic gasoline injectors for manifold gasoline injection.

Keywords: AUTOMOTIVE, INJECTOR, PARAMETERS, INJECTION

1. Introduction

A general layout of a typical automobile electromagnetic gasoline injector is shown in Fig.1.

![Fig.1. General layout of a electromagnetic gasoline injector: 1-Inlet port; 2-O-ring; 3-Filter; 4-Cover; 5-Terminal; 6-Coil holder; 7-Coil; 8-Upper Housing; 9-Armature; 10-Spring; 11-Guide; 12-Needle; 13-Camera; 14-Lower Housing; 15-Internal O-ring; 16-Spacer Washer](image)

The fuel inlet port 1 and the lower housing 14 are sealed with O-rings 2, respectively, to the fuel rail and the manifold. The filter 3 is located immediately after the inlet port in the cover 4. The cover is provided with a housing for accommodating the electrical terminals 5 connected to the winding 7 located on the coil holder 6. The upper housing 8 together with the lower housing closes the magnetic circuit. The housings are made of steel with corresponding strength, electromagnetic and anti-corrosion properties.

Upon feeding the control signal, the armature 9 draws the guide 11 and the associated needle 12 by collapsing the spring 10 and the fuel passing through the injector interior and the open seat of the chamber 13 is injected through two holes Ø 0.15 mm. When the signal is interrupted, the spring returns the needle to the starting position, whereby the needle seals the seat in the chamber with its front head and interrupts fuel injection through the spraying holes. Excess fuel that is at a higher pressure returns to the fuel rack. The positioning and sealing between the upper and lower housing is via the spacer washer 16 and the inner O-ring 15.

The ECU driver [2,5] (most commonly the Motronic system) actuates the injector control signal (Fig. 2, diagram a). The current in the winding of the electromagnet increases (diagram b) and this leads to the needle lifting (diagram c). The maximum lift (full stroke) of the needle is achieved after \( t_{pk} \) (pickup time) [2]. The fuel is injected as soon as the needle starts to rise from the sealing seat. The total amount of injected fuel for one injection varies according to the characteristic shown in diagram d.

![Fig.2. Activation characteristics: a-trigger signal; b-current through the winding; c-stroke of the needle; d-quantity of fuel injected](image)

The current through the winding decreases to zero when the control signal is terminated. The inertia of the moving parts (guide, needle, spring) causes the injector to close but with some delay. The injector closes completely after \( t_{dr} \) (drop-out time) [2]. When the injector is fully open, the amount of spraying fuel is proportional to time. The non-linear part of the injector opening and closing characteristic \( t_{pk} \) and \( t_{dr} \) times must be compensated for the entire injector actuation period (injection time \( t_{inj} \), injection duration). The speed at which the needle is lifted also depends on the battery voltage.

A stainless steel is used to produce metal elements that come in contact with the fuel (i.e. gasoline) to ensure stable operation of the nozzle [2].

2. Approach

The force \( P \) with which the electromagnet attracts the guide and a related needle is determined by the formula [3]:
The electromagnetic parameters of the injector are presented in Table 1 together with the basic mechanical and hydraulic parameters.

According to the above-mentioned dependencies calculations were made for the determination of the electromagnetic parameters, taking into account the influence of the voltage of the battery at the start of the engine. The minimum, nominal and maximum values of the voltage (Umin, Un, Umax), the current (Imin, In, Imax) and the electromagnetic force (Pmin, Pn, Pmax) are given in Table 1.

The calculation results for the electromagnetic force P in dependence on the stroke of the needle δ are given in Table 2. Table 3 gives computational results for the electromagnetic force P according to time t.

Figure 4 shows the change in working current I, A.

The value of the electromagnetic force P for the three voltage values is calculated with a fully closed needle or maximum needle stroke, i.e. at δ = 1.00 mm. This is done in order to determine a force reserve for propelling the needle.

The maximum current value is reached for about t = 0.015 s, which applies to all three characteristics.

The time to reach the maximum value of electromagnetic force is shown in Figure 6. The maximum value of electromagnetic force is reached for a time equal to that of the operating current, and has the same nature of increase.

In this way, the specific value of the electromagnetic force $P$ can be determined for a particular interval and a period of time, as well as determining the time $t_{\text{min}}$ to reach the required minimum value of the electromagnetic force $P_{\text{min}}$ for the opening of the needle. Further it may be aligned with the frequency mode of the engine and hence be recorded in the control algorithm of the management system.

**4. Parameters evaluation**

It is of the utmost importance that the injector provides the required cyclic fuel quantity at the right time and with the exact predetermined angle of advance of the injection. In other words, the performance of the injector defined by the minimum electromagnetic force $P_{\text{min}}$ and the minimum trigger time $t_{\text{min}}$ [5]. The minimum electromagnetic force is defined in the previous section. The minimum trigger time is related to the needle movement rate and is determined by the following dependencies.

The needle motion is determined by:

$$V_{n} = \frac{P_{\text{min}} - F}{m_{n}} \Delta t + V_{n_1}, \text{ m/s},$$

where: $\Delta t$ –time interval for needle motion, $s$; $V_{n}$ – needle speed at $i$ interval, $m/s$.

At the beginning of the opening of the needle and the reduction of the gap $\delta$, the electromagnetic force $P$ increases by exponential law and theoretically bends to infinity at $\delta = 0.00$ mm (fully open needle) - fig.5.
The distance $X$ traveled by the needle is determined of:

\[ X_{ni} = \frac{P_{i-1} - F}{m_i} \Delta \frac{X}{2} + V_{i-1} \Delta t + X_{n-1}, \text{ m.} \]

where: $X_{ni}$ - distance traveled by the needle at $i$ interval, m.

After replacing the values for the electromagnetic and spring force and the needle mass, values of time $t$ are set, the minimum time $t_{min}$ being defined as corresponding to that of $X_{n} > 0$ mm.

The calculated minimum trigger time $t_{min}$ is compared to actual oscillograms of the injector operation along with the electronic control unit of the engine test bench. Oscillograms were taken when the engine was started (Fig.7), idle (Fig.8) and acceleration (Fig.9).

Fig.7. Oscillogram of the injector control signal at the engine start

Fig.8. Oscillogram of injector control signal at the engine idle speed

Fig.9. Oscillogram of injector control signal at the engine acceleration

According to the oscillograms the fuel injection time $t_{inj}$ is as follows:

- start: $t_{inj} = 14$ ms;
- idle: $t_{inj} = 3$ ms;
- acceleration: $t_{inj} = 12$ ms.

It should be noted that the recorded oscillograms are at zero engine load. When increasing the load on the engine, the value of the $t_{inj}$ also increases.

It can be seen that $t_{min}$ and $t_{inj}$ have comparable values only at engine idle. In all other cases $t_{min} < t_{inj}$ which means that the calculations performed are of sufficient reliability.

5. Conclusion

An approach for calculating the electromagnetic parameters of automotive electromagnetic gasoline injectors for manifold injection (multi-point injection) is presented.

The criteria minimum trigger time $t_{min}$ and minimum electromagnetic force $P_{min}$ are proposed to assess the electromagnetic parameters of automotive electromagnetic gasoline injectors for manifold injection.

RESOURCES

Аннотация. Для обеспечения безопасности движения поездов и увеличения межремонтного ресурса грузовых вагонов необходимо не просто устранять причины допущенных нарушений безопасности, но и создавать эффективную систему TO и R вагонов на основе глубокого анализа статистической информации о дефектах. В этом статье проведено исследования для получения закономерности распределения риска транспортного происшествия, когда вагон эксплуатируется с боковой рамой, у которой имеется критический дефект. Основные дефекты боковых рам, которые выявляется при техническом обслуживании и ремонта, являются трещины и износы. Поэтому выполнения по определению статистическая оценка стойкости боковых рам грузовых вагонов с критическим дефектом является актуальной задачей перед вагонным хозяйством.

Ключевые слова: ТЕЛЕЖКА, БОКОВАЯ РАМА, ДЕФЕКТ, ОТКАЗ, ТРЕЩИНА, ИЗНОС, ЭКСПЛУАТАЦИЯ, ГАММА-РАСПРЕДЕЛЕНИЯ, НАРАБОТКА, СРОК СЛУЖБА, НАГРУЗКА, ЖИВУЧЕСТЬ, СТОЙКОСТЬ.

Введение. Эксплуатационные испытания подвижного состава в Азербайджане и в том числе странах СНГ показали, что самым слабым звеном вагона является тележка. Большинство выпускаемых вагоностроительными заводами грузовых вагонов оборудовались тележкой ЦНИИ-Х3, модели 18-100. В проведенными исследованиями показали, что тележка по многим параметрам не полностью отвечает эксплуатационным требованиям.

Нагрузки, действующие на тележки в эксплуатации носят случайный характер и зависят от многих факторов. Поэтому неисправности и отказы также носят случайный характер [1,2]. Практика эксплуатации показывает, что около 20-22 % грузовых вагонов поступают в текущий отцепочный ремонт по отказам сборочных единиц тележек рис 1. Все неисправности (дефекты) тележек в эксплуатации можно разделить на три группы: дефекты усталостного происхождения, дефекты, связанные с нарушениями условий эксплуатации, износы трущихся поверхностей деталей тележек. Боковая рама и надрессорная балка является основным базовым деталей тележек вагонов и принимает все нагрузки от кузова вагона.

Рис 1. Распределение отцепок грузовых вагонов в текущий отцепочный ремонт по неисправностям тележек.

Рис 2. Распределение неисправностей боковых рам по срокам эксплуатации.

При техническом обслуживании грузовых вагонов боковых рамках выявляется трещины в следующем порядке: 1-трещины в зонах наружных углов боковых проемов, 2-трещины в зонах над боковыми проемами, 3- трещины в зонах внутренних углов боковых проемов, 4- трещины в зонах наклонных поясов, 5- трещины в зонах верхних углов рессорного проема, 6- трещины в зонах нижних углов рессорного проема,

Рис 3. Дефекты в боковой раме, разрешенные ремонтовать при плановых видах ремонта

В период с 2010 г. по настоящее время на сети дорог произошло 142 случаев изломов боковых рам тележек, в том числе изломы боковых рам тележек модели 18-100, повлекших за собой сходы с рельсов подвижного состава, и эта цифра продолжает расти (рис. 4). Главной причиной указанных случаев стало несовершенство технологии изготовления литых деталей тележек и, как следствие, низкое качество. В результате возникла серьезная угроза безопасности движения поездов, а также возросли убытки предприятиях железных дорог и других участников перевозочного процесса. Под безопасностью вагона следует понимать его свойство, заключающееся в предсказуемости его переходов в процесс эксплуатации в аварийные состояния, которые могут привести к непоправимым последствиям для человека и природной среды [4].
Под опасным отказом вагона следует понимать событие, состоящее в переходе его в аварийное состояние, которое при наложении на него рокового сочетания обстоятельств может немедленно привести к транспортному происшествию с весьма тяжелыми последствиями - к аварии или крушению поезда. Переход конструкций, в том числе вагонных, в это состояние происходит из-за недостаточной прочности или ее исчерпании в процессе эксплуатации, низкого качества и несоответствия ремонта и так далее.

Вследствие указанных выше причин присутствие брака в работе осмотрщиков вагонов и определенной стойкости конструкции вполне реальная ситуация, когда вагон какое-то время находится в так называемом скрытом (для всех) аварийном состоянии, но используется в перевозочном процессе как исправный.

Пребывание вагона в скрытом аварийном состоянии может завершиться постановкой его в плановый ремонт, обнаружением опасного повреждения узла вагона за некую отрезок времени в текущем ремонте или переходом вагона в очевидное для всех состояние полной потери работоспособности с соответствующими последствиями той или иной тяжести.

Как правило, при разработке модели эксплуатационной безопасности подвижного состава (вагон) выделяется три этапа получения показателя риска аварии поезда:

Первый этап - получение точечных оценок параметров функции распределения. В выполненной научной работе рассмотрена модель стойкости боковой рамы грузового вагона, эксплуатирующейся в условиях нормальной эксплуатации грузовых вагонов в странах СНГ» с наличием критического дефекта, а именно трещины (или литейного дефекта), ставшей причиной ее излома в организованном грузовом поезде. В соответствии с стандартом [4] под критическим дефектом понимается дефект, при наличии которого использование детали машин или продукции невозможно или недопустимо.

В процессе формирования массива эмпирических данных учитывались только те случаи изломов боковых рам, которые происходили за последний дефект, а именно трещины (или литейного дефекта), ставшей причиной ее излома в организованном грузовом поезде. **Таблица 2.** Определение эмпирических данных - сроков службы боковых рам с критическим дефектом до момента разрушения по закону гамма-распределения.

Таким образом, в результате проведенного исследования получен закон распределения риска транспортного происшествия для случаев, когда вагон эксплуатируется с боковой рамой, у которой имеется критический дефект. Случайные величины фактического срока службы и наработка боковой рамы до излома - подчиняются закону гамма - распределения.

**Выводы.** В статье показано основные неисправности тележек грузовых вагонов. Проанализированы данные по изломам боковых рам тележек грузовых вагонов в период с 2010 по 2017 гг., в результате полученных массив данных по живучести боковых рам с критическим дефектом как по наработке, так и по сроку службы. В результате аппроксимации эмпирических данных установлено, что случайные величины фактического срока службы боковых рам с критическим дефектом подчиняются закону гамма - распределения. Определены соответственно значения числовых характеристик параметров гамма - распределения.

**STATISTICAL ASSESSMENT OF THE RESISTANCE OF THE LATERAL FRAMES OF THE CARTS OF TRUCK CARS WITH CRITICAL DEFECT**

Elyazov Israil Shukur oglu, Azerbaijan Technical University, Az1073, Azerbaijan, city Baku. Avenue G.Jaweed house 25, department «Operation of railway transport», cand.tech.scin. associate prof., tel; +994(50) 664 42 71, E-mail: elyazov-62@mail.ru

The article shows the main malfunctions of freight car trucks. The data on the breaks of the side frames of freight car trucks in the period from 2010 to 2017, as a result of the obtained data on the survivability of side frames with a critical defect both in terms of operating time and service life, are analyzed. The result of approximation of empirical data has been found accidental development of the side frames with the critical defect are subject to the low of the gamme distribution. Results of numerical characteristics of the distribution parameters are determined accordingly.

Abstract: This paper presents a design proposal for an electronic throttle control system intended for the experimental light hybrid-electric vehicle. This vehicle was made in the scope of ongoing student project of developing and creating a light hybrid-electric vehicle as a platform for educational and research work. In the present case, ATV/quad-vehicle engine is used, where the throttle command of IC engine was originally realized using mechanical linkages and cable. In order to fully exploit hybrid drive potentials, control of both IC engine and electric hub motors had to be exerted by using single accelerator pedal. For this purpose, the original IC engine control system had to be replaced by an electric motor actuator that uses control signal from accelerator pedal used for electric motors control. The prototype of mechanism that converts rotation of electric motor actuator output shaft into linear displacement of the needle valve was also designed and produced applying 3D printing technique.

Keywords: ELECTRONIC THROTTLE CONTROL, ELECTRIC DRIVE, HYBRID DRIVE, PROJECT-BASED LEARNING, STUDENT PROJECT

1. Introduction

The aim of Electronic Throttle Control (ETC), alongside improving vehicle’s performance, is reducing emissions and improving fuel economy. Unlike traditional throttle system that uses mechanical linkage between the acceleration pedal and the throttle, ETC uses several sensors and actuators for regulating airflow in the intake manifold [2]. This project implies a mechatronic approach as it was designed as a combination of different engineering fields (e.g. mechanics, electronics, and programming).

A vehicle that was developed through student project, is configured as a parallel hybrid with IC engine power on the rear axle and two electric hub-motors on the front axle. Such drivetrain configuration enables different operating modes. For example, the vehicle can be driven using either the IC engine or the electric drive independent of each other. Further, these two power sources can work simultaneously, whereby two different approaches can be distinguished. One of them is the economic mode, where IC engine operates around the most efficient energy conversion point, while electric motors provide additional torque required for a smooth and stable drive or moderate acceleration required by the driver. The other one is achieving maximum torque, using full throttle control for the IC engine and torque boost provided by the electric drive. Finally, regenerative braking can be used to further improve the overall fuel economy. Carburetor control is based on the needle valve, so that special features of such a system had to be taken into account in the scope of the designing process. For this purpose, the original IC engine control system had to be replaced by an electric motor actuator that uses control signal from accelerator pedal used for electric motors control.

Design of such conversion is the main goal of this work. Designing process for the prototype of the mechanism that converts the rotation of electric motor actuator output shaft into linear displacement of the needle valve will be described. 3D printing technique has been utilized in realization of the project. The new control system also uses the controller with the appropriate software which converts the control signal to the actuator displacement.

2. Results and discussion

There are three types of hybrid drive structures

• Serial
• Parallel
• Split power hybrid drive (has a combination of both properties serial and parallel hybrid drives) [3]

The vehicle described in this paper is constructed as a parallel hybrid drive gaining power from two different power sources. Two in-wheels electric motors are controlling the front axle and the IC engine is controlling the rear axle. By using parallel drive configurations those two power sources can work either simultaneously or independently. Both current vehicle and powertrain components are shown in Figures 1, 2 and 3 [1].

Due to having two power sources, this vehicle contains two separate acceleration pedals. This configuration is to be improved by implementing ETC system that would result with usage of conventional, driver-friendly single pedal system and so-called throttle-by-wire control. ETC system’s task is to provide an electronic connection from the acceleration pedal to a microcontroller up to the electric motor actuator, which serves to power the excenter mechanism that is directly connected to a carburetor.

Fig.1 Current appearance of the vehicle [1]
There are various carburetor types, most common ones are with the throttle valve, and however, carburetor described in this paper is one with the needle valve, which makes it rare in the terms of automatization. The first approach was to model simplified models of acceleration pedal and the carburetor which was done in Catia V5 Student version (Fig. 3). The idea was to build a gear rack mechanism that converts rotary to linear motion, but it was eliminated due to printing difficulties. A mechanism that was easiest to print, yet equally efficient, was an excenter mechanism (Fig. 4). This mechanism only needs to overcome the spring force because needle valve configuration is simpler than the throttle valve configuration.

Electric motor actuator, suitable for this type of application was a DC servo motor (model micro servo sg90 was used) because of it’s a quick response to fast changing input signals. There was no need for an additional sensor, like the linear potentiometer, because chosen servo motor already has a potentiometer in its housing, which acts as a sensor. Servo motor is controlled via PWM signal through an Arduino microcontroller and signal gained from the servo’s potentiometer is used as a feedback meaning this prototype is controlled in a closed loop. Additionally, input signal was received from the potentiometer (used as a substitution for the real acceleration pedal) which determined acceleration pedal’s position by giving the output voltage depending on a pedal’s angle i.e. force made while stepping on a pedal.

Ultimaker 2 extended 3D printer was used for printing the prototype (Fig. 4) using ABS (Acrylonitrile Butadiene Styrene) filament and technology named fused filament fabrication (FFF). Firstly the filament is extruded, heated to a working temperature and then forced through the heated nozzle, which diameter is smaller then 1 mm. While nozzle stays fixed, printer’s platform beneath the nozzle is moving in X/Y/Z directions, allowing fresh layers to fuze on top of the previous, cooled ones. All together, approximate time for printing the prototype was around four hours.

3. Conclusion

Comparison of the working principles between the throttle and a needle valve results with the conclusion that the needle valve mechanism is much simpler meaning it requires simpler control. The prototype used in this paper was controlled without any PID controller unlike the one in [2], but adding the PID controller could be accomplished in future development. Further improvements that could be realised are adding more sensors for getting more reliable output signals and designing a control logic in Matlab/Simulink by using model-based technology. Additional tests could be done, based on considering what external impacts could cause unwanted mechanism behavior such as excessive vibrations, environmental conditions, wear of materials, etc.

4. Acknowledgments

This paper was done as a part of the researches on the project TR35041 “Investigation of the safety of the vehicle as part of cybernetic system: Driver-Vehicle-Environment” and the project TR31046 “Improvement of the quality of tractors and mobile systems with the aim of increasing competitiveness and preserving soil and environment”, supported by Serbian Ministry of Education, Science and Technological Development.

Abstract: In this paper, the dynamics of acceleration and energy costs for cars with various types of inter-wheeled differentials are analyzed. The used dynamic models for drive with: a classical symmetric conical open differential, a fully locked differential, and limited-slip differentials for which the locking torque depends on the load or the relative speed of rotation are described. During the study, the ratios of the adhesion coefficients under the right and left sides were varied. As a result of the work, tasks are formulated for further more detailed analysis of limited-slip differentials.

KEYWORDS: INTER-WHEELED DIFFERENTIALS, LIMITED-SLIP DIFFERENTIALS, ENERGY EFFICIENCY, ACCELERATION DYNAMICS.

1. Introduction

The need for inter-wheeled differentials arose immediately after the appearance of the first vehicles with a two-wheel drive on the same axle. The most noticeable need was manifested when the car turns and drives on roads with irregularities. The absence of an inter-wheeled differential in transmissions leads to the appearance of power circulation, unjustifiably large additional loads on the drive axle and wheels, increased fuel consumption, and large tire wear. With the invention of the classical conical symmetrical inter-wheeled differential, these problems were solved. However, other problems associated with the phenomenon of slippage in severe road conditions are appeared. Naturally, there was a large number of technical solutions to this challenge that somehow smoothed out the problem, but did not solve it in a all-inclusive manner.

The simplest and chronologically the first solution to combat slippage of one of the driving wheels was a complete interlock of the differential on demand (manual control). As a rule, the locking is effected by a gear or cam clutch. In this case, the process of turning the clutch on or off requires a complete stop of the vehicle. In severe road conditions, this requires the driver to activate the described device in advance. Such a locking provides maximum traction capabilities of the wheeled propeller, since it allows to transmit up to 100% of the power to any of the wheels, which is able to accept it under the conditions of adhesion to the supporting surface. If the implementation of a complete locking is structurally solved using a friction clutch, it no longer requires the vehicle to stop. This design is relatively easy to automate, but is usually associated with an increase in the size and weight of the differential and the main gear, as well as a decrease in ground clearance. Full locking of the differential requires mandatory shutdown after entering to the road with a hard surface or a dry dirt road.

The second solution to the slip problem was the invention of a whole group of self-locking differentials or limited-slip differentials. Depending on the design, these may be Torque sensitive differentials (HLSD) or Speed sensitive differentials. In recent decades, there have been design solutions in which the degree of blocking is electronically controlled by a given algorithm, as well as drives in which the traction control system directly controls the torque applied to each drive wheel. Especially effectively they work in the case of electric or hydrostatic motor-wheels.

In the scientific and technical literature, the distribution of power between wheels and axes in modern cars is given a lot of attention. There are a large number of publications describing the work of different types of differentials [1–6] and considering a scientific approach to determining their optimal characteristics [7–10]. However, in most cases when analyzing the differentials for cars operating in difficult road conditions and off-road, the issues of proper patency are considered.

The papers [11–14] also consider the efficiency of using differential drives primarily for all-wheel drive vehicles. Especially intensive in this direction works the scientific school headed by Andrei Keller from the South Ural State University (Russian Federation). However, the complex comparative analysis of the dynamics of acceleration and losses on slippage for various types of inter-wheeled differentials has not been found in the literature. This issue, despite the rapid development of electronic control systems and individual electric drives, remains relevant for military wheeled vehicles and all-wheel drive vehicles of multi-purpose use, in which the full lock of differentials with manually operating is still most often used.

2. Materials research.

2.1 Formulation of the Problem

In this paper, the authors posed the task of performing a comparative analysis of the classical (open) conical symmetric differentials, of the limited-slip differentials, of the traction control systems (TCS) based on anti-lock brake systems (ABS) and of the completely locked differentials, from the point of view of the dynamics of the acceleration of the machine, the magnitude of the slip losses and the magnitude of the moment of resistance to turning. The study was carried out for vehicles under conditions where dry and pure asphalt concrete is located under one of the sides of the machine, and under other side the coupling properties of the road surface change from dry asphalt to an icy road. The car was considered as all-wheel driven, but the type of the inter-axle differential and the method of power distribution between the axes at this stage of the research was adopted rigid (blocked). In this case, the wheel propeller on each of the axes can realize the traction force proportional to the coupling weight. This was done to assess the effect on the investigated factors of the imbalance of the adhesion coefficients under the sides and the specific power for any single axis.

2.2 The Description of the Mathematical Model of the Vehicle Acceleration and the Calculation Assumptions

Accepted Assumptions, Baseline Data and Variable Parameters.

1) The entire weight of the all-wheel-drive vehicle is reduced to one axis and is considered constant during the entire acceleration time. Vibration processes in the suspension of the vehicle are not considered.
2) We considered a plane model of vehicle rectilinear motion on a horizontal surface during acceleration without lateral displacement and skidding.
3) The change in the instantaneous radius of the driving wheel with respect to the static radius under the influence of the driving torque and centrifugal forces is not taken into account.

4) The resistance of air during acceleration is not taken into account, since acceleration is considered up to 10 m/s

5) We accept that the left wheel is always in better conditions of grip with the road than the right one.

The work examines the acceleration from the place of the all-wheel drive wheeled armored personnel carrier BTR-4, which is in conditions when the adhesion coefficient of wheels with the road under left side meets the dry clean asphalt \( \phi_L = 0.8 \), and under right side the adhesion coefficient varies in different arrivals from dry asphalt \( \phi_R = 0.8 \) to the icy road \( \phi_R = 0.1 \).

The middle coefficient of resistance to movement (drag coefficient) also changed in various races from dry clean asphalt \( f_m = 0.02 \) for tires with adjustable pressure) to wet dirt road \( f_m = 0.08 \).

The drive to the differential was stepless with constant power, which was limited to the maximum torque with a value providing a specific traction force equal to unity. This limited the slippage of both wheels during the acceleration process.

For carrying out the calculations, the data needed were taken using the example of the wheeled armored personnel carrier BTR-4, namely:

- armored vehicle weight \( G = 24 \) tons;
- static wheel radius at normal tire pressure \( R_n = 0.525 \) m;
- reduced moment of inertia of a wheel with a wheel gear and a semiaxis \( I_{o_0} = 1.5 \) kg m²;
- moment of inertia of the drive (engine and transmission) in the first gear \( I_{o_1} = 5 \) m²;
- the maximum torque on the differential case when the specific thrust force is limited to unity \( M_{\text{in}}^{\text{max}} = 7275 \) Nm.

**Structure of the Mathematical Model.**

The calculation scheme for modeling the process of accelerating the machine is shown in Fig. 1. Here the following forces and torques are indicated:

- \( G_M \) - weight of the armored personnel carrier, per axle;
- \( N \) - normal reaction of soil (road) in the contact spot of one wheel;
- \( P_{Dr} \) and \( P_{Dl} \) - The traction forces realized on the left and right driving wheels that calculated as functions of the coefficients of slipping and grip on each of the wheels \( P_{Di} = f(\sigma, \phi_l) \);
- \( P_{Rl} \) and \( P_{Rr} \) - rolling resistance forces on the left and right driving wheels, calculated as the product of the mean under the right and left sides of the drag coefficient \( f_m \) and normal ground reaction \( N \);
- \( P_{Di} = P_{Ri} = N_{fr} \), where \( f_m = (f_t+f_r)/2 \);
- \( M_{in} \) - input (driving) torque on the differential case;
- \( \omega_{in} \) - angular velocity of the input link (differential case);
- \( I_{l} \) - the moment of inertia of the differential case and the associated rotating parts of the drive;
- \( I_{r} \) and \( I_{M} \) - torque on the left and right driving wheels; \( M_{fr} \) and \( M_{r} \) - angular speeds of rotation of the left and right driving wheels;
- \( L_{r} \) and \( L_{l} \) - moment of inertia of the left and right driving wheels with a wheel gear and a semiaxis;
- \( V_M \) - linear speed of the machine along the coordinate axis \( X \).

Three generalized speeds are identified in the model:

- \( \omega_{in} \) - angular velocity of the input link (differential case);
- \( \Delta \omega \) - the difference between the angular velocities of the left and right semi-axes or driving wheels (in the absence of wheel gears), determined by formula \( \Delta \omega = \omega_{fr} - \omega_{fr} \);
- \( V_M \) - linear speed of the machine along the coordinate axis \( X \).

For these generalized velocities, according to the d’Alembert principle (Newton’s second law), differential equations are constructed that describe the accelerated motion of these masses:

\[
\frac{d\omega_{in}}{dt} = \frac{M_{in} - M_{fr} - M_{fr}}{I_{in} + I_{fr} + I_{r}},
\]

\[
\frac{d\omega_{fr}}{dt} = \frac{P_{Di} + P_{Rl} - P_{Di} - P_{Rr}}{G_M/8},
\]

where \( \eta_{in} \) - coefficient of efficiency of differential with conical straight teeth \( \eta_{in} \approx 0.95...0.96 \); \( M_{fr} \) - additional frictional torque, formed on the limited-slip differentials or on brake mechanisms of ABS to prevent intensive slippage.

![Figure 1 – Calculation scheme for modeling the process of the machine accelerating](image-url)
For differentials in which the degree of blockage depends on the difference in the speed of the wheels rotation \( M_k = k_w \Delta \omega \) or \( M_k = k_v \Delta \omega^2 \) depending on the type of differential, where \( k_w \) – corresponding coefficient of proportionality.

When using TCS based on ABS, the algorithm for determining the additional frictional moment is as follows:

- if \( \Delta \omega < \Delta \omega_b \), then \( M_{f_k} = 0 \); 
- if \( \Delta \omega > \Delta \omega_b \) and \( \frac{d \Delta \omega}{dt} > 0 \), then there is an increase in the frictional moment with a high speed in proportion to time \( M_{f_k} = k_t f \); 
- if \( \Delta \omega > \Delta \omega_b \) and \( \frac{d \Delta \omega}{dt} < 0 \), then the value of the frictional moment is fixed from the previous calculation step and does not change.

It should be noted that when using TCS based on ABS, in equation (1) the additional friction moment is also added, since it additionally loads the drive:

\[
\frac{d \Delta \omega}{dt} = \frac{M_w - M_1 - M_2 - M_{f_k}}{I_n + I_1 + I_r}.
\]

The acceleration of the machine was carried out to a speed of 10 m/s, while at each step of solving the system of differential equations the work performed by the drive was calculated, summing over the entire period of acceleration.

2.3. Calculations results

In fig. Figures 2-5 show the calculation results for the various inter-wheeled differentials, described above, for the BTR-4 armored personnel carrier. On all graphs, the horizontal scale is presented in relative units \( \Delta \phi = \frac{\phi_n}{\phi_i} \in [0.125; 0.5] \), characterizing the balance of adhesion coefficients under the sides. The right boundary of the range was calculated to \( \Delta \phi = 1 \), but due to the low information content on this site was limited to \( \Delta \phi = 0.5 \).

Calculations were carried out for the following types and characteristics of differentials: \( w_{10}, w_{20}, w_{40} \) – differentials in which the locking factor depends on the difference in wheel speeds with coefficients, respectively: \( k_w = 10, 20, 40 \text{ Nm s}^{-1} \); \( qw_{05}, qw_{1}, qw_{15}, qw_{2} \) – differentials in which the locking factor depends on the square of the difference in wheel speeds with coefficients, respectively: \( k_w = 0.5, 1.0, 1.5, 2.0 \text{ Nm s}^{-2} \); \( M_{02}, M_{04}, M_{06} \) – differentials in which the locking factor depends on the load with coefficients, respectively: \( k_m = 0.2, 0.4, 0.6 \); TCS – traction control system based on ABS with \( \Delta \omega_b = 5 \text{ s}^{-1} \), \( k_f = 20000 \text{ Nm/s} \).

In all graphs, the results are presented in relative units relative to the indicators obtained for the blocked differential. Since the blocked differential has the best performance in straight-line motion, all the values shown in the graphs are greater than one.

The graphs do not show curves for an open conic differential, since they differ significantly from other indicators and have a bad effect on the scale. For average coefficients of resistance to movement \( f_m = 0.02 \) and \( f_m = 0.08 \), the relative excess of the acceleration time to 10 m/s with an open differential is 1.91 and 5.19 respectively. And the relative excess of energy costs for the same conditions is 2.13 and 5.85 respectively.

All the charts in the work, as mentioned earlier, were built for the wheeled armored personnel carrier BTR-4, which as standard has a specific power of 14.58 kW / t (19.83 hp / t).

This moment is significant, since the change in specific power, both in the smaller and in the larger direction, substantially distorts the obtained graphical dependencies not only in absolute, but also in relative dimension.

3. CONCLUSIONS

In accordance with the goals and objectives set for the results of the work done, the following conclusions can be drawn:

1) Non-blocked open conic differentials and fully-locked differentials were considered only to determine the boundaries of the worst and best overclocking performance indicators.

2) The comparative data obtained are given for the average values of the system adjustment factors. Therefore, for final conclusions about the advisability of using a particular limited-slip differentials or TCS based on ABS, taking into account the influence of the differential on the controllability of the machine, it is necessary to optimize by the setting factors.

3) From the preliminary consideration of the problem, it can be stated that all the limited-slip differentials in terms of the efficiency of straight-line acceleration are close to the characteristics of the locked differential in the following sequence:
   - fully-locked differentials;
   - differentials in which the locking factor depends on the difference in wheel speeds;
   - differentials in which the locking factor depends on the square of the difference in wheel speeds;
   - differentials in which the locking factor depends on the load;
   - TCS – traction control system based on ABS;
   - open conic differentials.

4) Differentials with TCS based on ABS are most appropriate for relatively small values of imbalance of adhesion coefficients along the sides of the machine and to integrate them with systems for maintaining directional stability, which allow, depending on the situation, to change the values of the coefficients of the system settings.

5) Limited-slip differentials, in which the blocking moment depends on the square of the difference in the speed of rotation of the wheels, can have high energy parameters during acceleration with minimal negative impact on the controllability of the machine and at the same time rely not on electronic control systems, but on their own internal automatism.

Abstract: The paper presents numerical analysis of in-cylinder pressure and temperature change for naturally aspirated gasoline engine and two of its upgrades - upgrade with turbocharger only and upgrade with turbocharger along with air cooler. Numerical analysis was performed with 0D (zero-dimensional) numerical model. In-cylinder temperatures, for each engine rotational speed, are the highest for engine upgraded only with the turbocharger. The highest observed in-cylinder temperature of turbocharged engine was obtained at 5000 rpm and amounts 2542.4 °C. In-cylinder pressures are the highest for engine upgraded with turbocharger and air cooler for all rotational speeds except the highest one. The highest observed in-cylinder pressure of a turbocharged engine with air cooler was obtained at 5000 rpm and amounts 129.7 bars. Presented analysis showed that the selected air cooler can be improved at highest engine rotational speed.

KEYWORDS: NUMERICAL SIMULATION, IN-CYLINDER PROCESS, GASOLINE ENGINE, ENGINE UPGRADE

1. Introduction

Gasoline engines with spark ignition are one of the known types of internal combustion engines [1]. Its characteristics and specifications are dependable on many parameters.

Control and regulation systems are essential elements of any gasoline engine, which ensures engine proper operation. Yar et al. [4] developed and presented first principle based control oriented model of a gasoline engine which includes multi-cylinder dynamics.

Nonlinear constrained torque control system for a gasoline engine developed Kang et al. [5].

Alternative fuels for gasoline engines are investigated by many authors. Elfasakhany [6] performed gasoline engines performance evaluation and pollutant emissions analysis by using ternary bio-ethanol-iso-butanol-gasoline blends. Effect of addition of hydrogen and exhaust gas recirculation on characteristics of hydrogen gasoline engine investigated Du et al. [7].

Turbocharging process which uses the energy of engine exhaust gases is one of the best methods for improving naturally aspirated engine operating parameters and characteristics. Modeling and control of the air system for a turbocharged gasoline engine investigated Moulin and Chauvin [8]. An upgrade of turbocharging process involves air cooler after charger, in order to perform proper cooling of air which enters into the engine cylinders [9]. Air cooling allows an increase of engine volumetric efficiency and decrease of maximum in-cylinder temperature when compared to the engine which has only the turbocharger.

In this paper is presented numerical analysis of in-cylinder pressure and temperature change for naturally aspirated gasoline engine and two of its upgrades - upgrade only with turbocharger and upgrade with turbocharger along with air cooler. Numerical analysis was performed with 0D (zero-dimensional) numerical model. It was obtained that in-cylinder temperatures, for each engine rotational speed, are the highest for engine upgraded only with the turbocharger. In-cylinder pressures are the highest for engine upgraded with turbocharger and air cooler for all rotational speeds except the highest one. Presented analysis showed that air cooler, selected in this analysis, can and should be improved at highest engine rotational speed.

2. Numerical model equations for in-cylinder temperature and pressure change calculation

Numerical model used for simulations is 0D (zero-dimensional) model presented by Medica [10]. 0D model is basically developed for simulation of diesel engines and after a while is upgraded on QD (quasi-dimensional) model [11] which results are presented in [12] and [13] for high-speed four-stroke diesel engine and in [14] for slow-speed two-stroke diesel engine.

To be able to simulate the operating parameters of a gasoline engine with the mentioned 0D model, the numerical model is modified in necessary elements which present differences in operating characteristics between gasoline and diesel engines. The modified 0D model is tested on several gasoline engines. For all analyzed gasoline engines and for its operating parameters were obtained deviations between producer specifications and numerical model results in the range of ± 3%.

Engine cylinder is presented as a separate control volume with walls was calculated by using an equation:

\[
\text{changes in cylinder walls} = \frac{\text{changes in cylinder walls}}{\text{gas volume}} + \frac{\text{changes in cylinder walls}}{\text{operating medium mass}}
\]

The cylinder pressure is determined from the gas state equation:

\[
\frac{dP}{d\varphi} = \frac{m_c}{V_c} \left( \frac{dV}{d\varphi} \right)
\]

The heat exchange between the working fluid and the cylinder walls was calculated by using an equation:

\[
\frac{dQ_{\text{wall}}}{d\varphi} = \sum \alpha_i A_{\text{wall}} \left(T_{\text{wall}} - T_{\text{cyl}}\right) \frac{dT}{d\varphi}
\]

where the mean heat transfer coefficient \( \alpha \) is calculated by an empirical equation presented by Woschni [16].

The combustion process is described by the heat release rate:

\[
\frac{dQ_{\text{comb}}}{d\varphi} = \frac{d\varphi}{d\varphi} \cdot \frac{m_c}{V_c} \cdot H_{\text{comb}} \cdot \eta_{\text{comb}}
\]

where the relative amount of combusted fuel increment \( d\varphi/d\varphi \) is calculated by equation presented by Vibe [17].

In the above equations, used symbols are: \( T = \) temperature, \( \varphi = \) engine crankshaft angle, \( m = \) operating medium mass, \( u = \) operating...
medium specific internal energy, \( Q = \text{heat amount}, V = \text{operating area volume}, p = \text{operating medium pressure}, h = \text{operating medium specific enthalpy}, \lambda = \text{excess air ratio}, W = \text{work}, R = \text{operating medium gas constant}, A = \text{control volume surface}, t = \text{time}, x = \text{relative amount of combusted fuel}, H_f = \text{fuel lower heating value}, n_{\text{comb}} = \text{efficiency of the combustion process}, 1_{pr} = \text{per one engine process}, f = \text{index for fuel}, w = \text{index for cylinder walls}, c = \text{index for engine cylinder}. Calorific gas properties \((u, h, \partial u/\partial \lambda, \partial u/\partial T)\) are modeled from the analytical expressions relating the temperature and gas composition \([18], [19]\). To make the simulation as fast as possible, it is assumed that in each engine cylinder happens the same change of pressure and temperature (phase-shifted).

3. Characteristics and specifications of base engine and both engine upgrades

The base engine is a four-stroke, high speed, naturally aspirated gasoline engine with direct fuel injection. The engine is designed for the usage in automotive applications. Base engine does not have any upgrades. Main operating characteristics and parameters of the base, naturally aspirated engine are presented in Table 1.

In Table 1 are also presented used cylinder materials and fuel basic specifications. Those data were the baseline for the correct heat exchange calculations in the engine cylinder.

Numerical simulation was firstly performed for the base, naturally aspirated engine. For base engine, along with other operating parameters, was obtained curves of change in cylinder temperature and pressure.

After simulation of base engine, it is performed the first base engine upgrade - inclusion of the turbocharger. Turbine and charger operating maps were described by polynomials and included in numerical simulation as a new subroutine along with equations for operating parameters calculation. During the engine upgrade with turbocharger engine base operating and geometrical characteristics remain unchanged, because one of the intentions was to investigate the possibility of engine proper operation with selected turbocharger without any base engine modifications. The main geometrical characteristics of selected turbocharger KKK 30.60/13.21 are presented in Table 2. Turbine and charger operating maps were obtained from the turbocharger producer.

| Charger inlet diameter | 0.0457 m |
| Charger outlet diameter | 0.0762 m |
| Intake turbine flowing surface | 0.0013 m² |

Numerical simulation of engine with included turbocharger was performed and along with other operating parameters, was obtained curves of change in cylinder temperature and pressure.

Second and final base engine upgrade was including air cooler after charger into engine simulation. Air cooler is air-air heat exchanger. In such heat exchanger numerical description, it is necessary to define heat exchanger cooling medium (air) mass flow, pressure loss and overall efficiency. For selected, standard charging air cooler, according to producer specifications \([21]\), air pressure loss and cooler overall efficiency were presented in relation to cooling air mass flow, Fig. 1.

![Fig. 1. Air cooler pressure loss and overall efficiency in relation to cooling air mass flow](image)

Final, third simulation was performed and along with other operating parameters, was obtained curves of change in cylinder temperature and pressure for the engine with both upgrades (turbocharger + air cooler).

4. Results of in-cylinder pressure and temperature change with discussion

Numerical model results of in-cylinder pressure and temperature change for all three simulated gasoline engine variants (base engine and two upgrades) are presented. Differences of analyzed engine variants are the most notable in high pressure and high temperature parts of in-cylinder process. In all the figures (from Fig. 2 to Fig. 7) it is presented the high temperature and high pressure part of in-cylinder process in relation to engine crank angle.

4.1. Cylinder temperature change for all simulated engine variants at different engine rotational speeds

At engine rotational speed of 3000 rpm, gasoline engine upgraded only with a turbocharger (without air cooler) gives the highest in-cylinder temperatures, with a peak value of 2491.2 °C. Engine upgraded with a turbocharger and air cooler at 3000 rpm gives lower in-cylinder temperatures than engine upgraded only with a turbocharger, but cylinder temperatures for engine with both upgrades are higher in comparison with a naturally aspirated engine. Peak in-cylinder temperature at 3000 rpm for the gasoline engine upgraded with a turbocharger and air cooler amounts 2471.8 °C. It can be concluded that air cooler causes notable decrease in cylinder temperature when compared to engine upgraded only with a turbocharger, Fig. 2. The lowest in-cylinder temperatures at 3000 rpm are achieved, as expected, for naturally aspirated engine. Peak in-cylinder temperature for naturally aspirated engine amounts 2443.8 °C at 3000 rpm.

![Fig. 2. Cylinder temperature change for the analyzed engine at rotational speed of 3000 rpm](image)

At engine rotational speed of 5000 rpm can be noticed significant differences in change of engine cylinder temperature for three simulated engine variants, Fig. 3. As before at 3000 rpm, at 5000 rpm the highest in-cylinder temperatures are obtained for the gasoline engine upgraded only with a turbocharger. Peak temperature value for engine upgraded with a turbocharger (without
has an engine with both upgrades and peak value of in-cylinder pressure for this engine variant amount 81.7 bars. An engine which is upgraded only with a turbocharger at 3000 rpm has in-cylinder pressure values slightly lower when compared to engine with both upgrades, while when this engine is compared with naturally aspirated engine one in-cylinder pressures are significantly higher. At the engine rotational speed of 3000 rpm, engine upgraded only with a turbocharger has peak in-cylinder pressure value equal to 77.4 bars.

In general, the same conclusions for in-cylinder pressure change for all three simulated engine variants, which are valid for engine rotational speeds of 3000 rpm, are also valid for engine rotational speed of 5000 rpm. The only difference can be seen in Fig. 6 - engine with turbocharger or an engine with turbocharger and air cooler has much higher in-cylinder pressures in comparison to naturally aspirated engine at 5000 rpm.

So, it can be concluded that turbocharging process causes a significant increase in engine in-cylinder pressure values especially at high engine rotational speeds. At the same high engine rotational speeds, with turbocharger and air cooler will be obtained the highest in-cylinder pressure values. At 5000 rpm, peak value of in-cylinder pressure for engine upgraded with turbocharger and air cooler amounts 129.7 bars, for engine upgraded only with a turbocharger it amounts 122.1 bars and for naturally aspirated engine amounts 72.3 bars.

At the highest engine rotational speed (6000 rpm) engine with turbocharger or an engine with turbocharger and air cooler also has significant higher in-cylinder pressures in comparison with a naturally aspirated engine, Fig. 7. The only difference which occurs at the highest engine rotational speed (in comparison to lower rotational speeds) is that the highest in-cylinder pressures are obtained for the engine only with a turbocharger, not as before for the engine with a turbocharger and air cooler. The reason of this occurrence can be found in Fig. 4. Decrease in in-cylinder temperature at 6000 rpm caused by air cooler after the turbocharger is significant, therefore simultaneously with an in-cylinder temperature decrease occurs decrease of in-cylinder pressure. So, only at 6000 rpm, the highest values of in-cylinder pressure will be obtained with engine upgraded only with a turbocharger.

This fact leads to conclusion that selected air cooler is not the best option for a simulated engine at the highest engine rotational speed. One of the future research directions of this engine and its

4.2. Cylinder pressure change for all simulated engine variants at different engine rotational speeds

Naturally aspirated engine at 3000 rpm has significantly lower in-cylinder pressures when compared to engine with turbocharger or to an engine with turbocharger and air cooler, Fig. 5. Peak in-cylinder pressure for a naturally aspirated engine, at 3000 rpm, amounts 63.2 bars. Again, the highest values of in-cylinder pressures at 3000 rpm
upgrades will surely be to find or design a new air cooler, which will operate at 6000 rpm as at lower rotational speeds. The limit during an air cooler exchange will surely be not to exceed usual values of cylinder maximal pressures (usual values are from 150 bars to 170 bars).

Peak values of in-cylinder pressure at 6000 rpm are: for naturally aspirated engine - 69.1 bars, for engine upgraded with turbocharger - 118.2 bars, and for engine upgraded with turbocharger and air cooler - 109.8 bars.

Fig. 7. Cylinder pressure change for the analyzed engine at rotational speed of 6000 rpm

5. Conclusions

This paper presents numerical analysis of in-cylinder pressure and temperature change for naturally aspirated gasoline engine and its upgrades - upgrade with turbocharger only and upgrade with turbocharger along with air cooler. It was analyzed by numerical 0D (zero-dimensional) model how engine upgrades influenced in-cylinder pressure and temperature change for the variety of engine rotational speeds.

In-cylinder temperatures, for each engine rotational speed, are the highest for engine upgraded only with the turbocharger. Engine upgraded with turbocharger and air cooler has lower in-cylinder temperatures than engine upgraded only with a turbocharger, what is expected because of air cooling before its entrance into engine cylinders. At the highest engine rotational speed (6000 rpm) air cooler significantly reduces in-cylinder temperature, so at the highest rotational speed, in-cylinder temperatures for an engine with turbocharger and air cooler are lower in comparison with naturally aspirated engine. As expected, the lowest in-cylinder temperatures are obtained for a naturally aspirated engine, for all engine rotational speeds except the highest one.

In-cylinder pressures are the highest for engine with two upgrades for all rotational speeds except the highest one. At 6000 rpm, air cooler after charger significantly reduces temperature of air which enters into engine cylinders and consequently reduces the values of in-cylinder pressure.

Engine upgraded only with a turbocharger has values of in-cylinder pressure slightly lower in comparison with an engine which has both upgrades, for each engine rotational speed except the highest one. When compared turbocharged engine with naturally aspirated - turbocharged engine has significantly higher values of in-cylinder pressure at each engine rotational speed.

Presented analysis showed that selected air cooler (engine with both upgrades) can be improved at the highest engine rotational speed (6000 rpm) what will be the guideline for future research.

Abstract: Exergy analysis of steam turbine governing valve from a super critical thermal power plant is presented in this paper. Governing valve was analyzed not only at the highest, but also on two partial steam system loads. The lowest valve exergy destruction is 3598 kW and is obtained at the highest steam system load, while at partial loads of 80% and 60% valve exergy destruction is 13550 kW and 21360 kW. Valves exergy efficiency increases with an increase in system load, from 95.58% at 60% of load to 97.87% at 80% of load. At the highest load, valve exergy efficiency is the highest and is 99.57%. Change in valve steam specific entropy increment (difference in steam specific entropy between valve outlet and inlet) can be used as a tool for quick assessment of valve losses change. The ambient temperature influence on governing valve exergy analysis is low, especially in the highest steam system load where the majority of valve operation can be expected.

KEYWORDS: GOVERNING VALVE, EXERGY ANALYSIS, AMBIENT TEMPERATURE, SUPER CRITICAL POWER PLANT

1. Introduction

Governing valves were used in any type of power plants (land based or marine power plants) [1]. The main function of governing valves is to reduce pressure of operating medium [2]. When the governing valves are used in steam power plants (super critical or sub critical) their operating medium is superheated steam.

Main operating characteristics of superheated steam governing valves are that with the pressure reduction the steam temperature also reduces. During the superheated steam pressure and temperature reduction, steam specific entropy increases [3]. As the governing valves are mounted before the turbine housing, its operation allows obtaining the desired superheated steam operating parameters at the turbine entrance [4], what is necessary for safe and reliable turbine operation.

The essential rule for the governing valve operation is that before and after valve specific enthalpy of operating medium remains constant [5] (the negligible difference in specific enthalpy can occur only due to losses). In such way, operating medium pressure is reduced while the energy content remains unchanged [6].

It is irrelevant to investigate governing valves from the energy viewpoint, because without any operating medium mass flow leakage, governing valves have energy efficiency of 100 % and energy power losses equal to zero.

In the scientific and professional literature analysis of any valve type is rare. After an extensive search, papers were found about the investigation of steam turbine control valves [7], or analysis of steam turbine control valve along with its actuation system [8]. In [9] authors analyzed compressible superheated steam flow rate through pressure reduction valves.

This paper analyzed steam turbine governing valve mounted on the high pressure steam turbine inlet in a super critical thermal power plant, through three different steam system loads. Measurement results of governing valve operating parameters (steam pressures, temperatures and mass flow rates) at each steam system load enable calculation of valve exergy power inputs and outputs, as well as valve exergy destruction and exergy efficiency. At each steam system load the differences in steam specific entropy between governing valve outlet and inlet are also calculated and presented, which is a good indicator of system load and valve losses. Governing valve was also analyzed during the ambient temperature change.

2. Analyzed governing valve operating characteristics

The analyzed governing valve is mounted on the high pressure turbine inlet in a supercritical thermal power plant, Fig. 1. The main function of governing valve is steam pressure reducing before steam enters in the turbine. In the land-based steam power plant, steam generator (or more of them) will usually produce superheated steam with the highest possible pressure and temperature (defined by the steam generator producer) during the majority of plant operation.

The changeable variable is usually the steam mass flow rate, which is the most important parameter for defining the power plant load.

Governing valves, which reduces steam pressure at the inlet of the first power plant turbine (high pressure turbine) are used for fine-tuning of power plant current load, while the steam energy content remains the same before and after the valve (the same steam specific enthalpy). Governing valves are important elements in any steam power plant, especially when plant operates at partial load.

Fig. 1. Analyzed governing valve position with marked inlet (1) and outlet (2) at the entrance of high pressure turbine from a super critical thermal power plant [10]

Steam turbine governing valves in thermal power plants are usually of Venturi type. Cross-section of the turbine steam chest along with governing valves and its main bar is presented in Fig. 2. The main bar mechanism is used for raising and lowering of the governing valves. All governing valves are not lifted at the same time equally, but periodically, one by one. Such opening regime is allowable by different lengths of each governing valve stem. The main bar lifting mechanism is usually driven by servomotor, as presented in Fig. 2.
3. Exergy analysis of a control volume

3.1. Governing equations for exergy analysis

Mass flow balance for a control volume in steady state disregarding potential and kinetic energy is defined according to [12] by an equation:

\[ \sum m_{IN} = \sum m_{OUT} \]  
(1)

Exergy exchange is based on the second law of thermodynamics [13]. The main exergy balance equation for a control volume in steady state [14] is:

\[ X_{heat} = P = \sum m_{OUT} \cdot e_{OUT} - \sum m_{IN} \cdot e_{IN} + E_{ex, D} \]  
(2)

where the net exergy transfer by heat \( X_{heat} \) at the temperature \( T \) can be defined, according to [15], by an following equation:

\[ X_{heat} = \sum (l - \frac{T_0}{T}) \cdot Q \]  
(3)

Specific exergy is defined [16] by an equation:

\[ e = (h - h_0) - T_0 \cdot (s - s_0) \]  
(4)

The exergy power of any flow stream [17,18] is defined as:

\[ E_{ex} = m \cdot e = m \cdot \left[(h - h_0) - T_0 \cdot (s - s_0)\right] \]  
(5)

The definition of control volume exergy efficiency depends on a control volume type and operation principle. In general, exergy efficiency of any control volume can be defined, according to [19,20], by an following equation:

\[ \eta_{ex} = \frac{\text{Exergy output}}{\text{Exergy input}} \]  
(6)

3.2. Exergy analysis of governing valve from a super critical thermal power plant

Necessary operating points for steam turbine governing valve exergy analysis are presented in Fig. 1. The required steam specific enthalpies and specific entropies are calculated by using measured steam pressures and temperatures from Table 1 with Nist-REFPROP 9.0 software [21].

Steam temperature and pressure change through the governing valve resulted with the change in steam specific entropy. Change in steam specific entropy resulted with a significant change of steam specific exergy, equation (4) and steam exergy power, equation (5). Change of governing valve outlet exergy power, in comparison with valve inlet, resulted with the change in the governing valve exergy destruction and exergy efficiency.

Mass and exergy balances for the analyzed steam turbine governing valve, according to Fig. 1, are:

- Governing valve mass flow balance:
  \[ m_1 = m_2 \]  
(7)

- Governing valve exergy balance:
  \[ E_{ex, IN} = m_1 \cdot e_1 \]  
(8)

- Exergy power output:
  \[ E_{ex, OUT} = m_2 \cdot e_2 \]  
(9)

- Exergy destruction (exergy power loss):
  \[ E_{ex, D} = E_{ex, IN} - E_{ex, OUT} = m_1 \cdot e_1 - m_2 \cdot e_2 \]  
(10)

- Exergy efficiency:
  \[ \eta_{ex} = \frac{E_{ex, OUT}}{E_{ex, IN}} = \frac{m_2 \cdot e_2}{m_1 \cdot e_1} \]  
(11)

The ambient state in the plant during the measurements was:
- pressure: \( p_0 = 1 \text{ bar} = 0.1 \text{ MPa} \),
- temperature: \( T_0 = 25 \text{ °C} = 298 \text{ K} \).

4. Measurement of governing valve flow streams

Measurement results of governing valve flow streams (at valve inlet and outlet) were presented in [10] for three different thermal power plant loads (load of 60%, 80% and full load – 100%). Table 1. From Table 1 it can be seen that at any load steam pressure and temperature remain constant at governing valve inlet, while steam mass flow rates at valve inlet decreases with a decrease in plant load. The steam temperature at governing valve outlet depends on the pressure reduction. Higher pressure reduction (lower steam pressure at valve outlet) will result with lower steam temperature at the valve outlet.

Table 1. Measured data of steam flow streams at the governing valve inlet and outlet [10]

*Streams numeration refers to Fig. 1.

From Table 1 it can be seen that power plant (steam system) load is mostly influenced with steam mass flow rate, which is the lowest at the lowest load and then increases up to the highest load.

Analyzed governing valve parameter which can also determine steam system load is the pressure reduction. The highest pressure reduction occurs at the lowest steam system load and for the analyzed valve it is 104.1 bar (reduction from 242.2 bar to 138.1 bar - load of 60%). Governing valve pressure reduction decreases with an increase in steam system load.

It can be concluded that governing valve pressure reduction and steam system load are reverse proportional, while the steam mass flow rate and steam system load are directly proportional.

5. Governing valve exergy analysis results with the discussion

5.1. Governing valve exergy analysis - based on the measurement results

Analyzed governing valve exergy power input and output change during the change in steam system load is presented in Fig. 3. An increase in steam mass flow rate, according to Table 1 and equations (8) and (9), is the most important reason for the increase of valve exergy power input and output during the increase in steam system load.

Governing valve exergy power input increases from 483538 kW at steam system load of 60%, to 643093 kW at a load of 80% and finally to 829807 kW at the highest steam system load of 100%, Fig. 3. Between the same steam system loads, valve exergy power output increases from 462178 kW to 629543 kW and finally it is 826209 kW at the highest steam system load.

The difference between valve exergy power input and output at each load represents valve exergy destruction (valve exergy power losses). From Fig. 3 and from presented values of valve exergy power input and output at each load it can be seen that those differences become lower and lower as steam system load increases. Governing valve has an operation principle as the most of other steam power plant components - the lowest exergy destruction will be obtained at the highest system load.

Exergy destruction of the analyzed governing valve, as a difference between exergy power input and output - equation (10), is the lowest at the highest steam system load and is 3598 kW, Fig. 4. As the steam system load decreases, valve exergy destruction increases and is 13350 kW at steam system load of 80%, while at
the lowest observed steam system load of 60% governing valve exergy destruction amounts 21360 kW.

Governing valve exergy efficiency, calculated according to equation (11) is the highest at the highest steam system load (99.57%) and then decreases with a decrease in steam system load. At partial steam system load of 80% valve exergy efficiency is 97.97%, while at the lowest load valve exergy efficiency is equal to 95.58%. It should be concluded that governing valve exergy efficiency has a very high values, even at a partial steam system loads.

Fig. 3. Change of governing valve exergy power input and output during the change in steam system load

As mentioned before from the presented measurement results, pressure reduction on the analyzed governing valve and steam system load are reverse proportional. Additional operating parameter of the analyzed governing valve can be used for detecting the change in steam plant load. This operating parameter is steam specific entropy difference between valve outlet and inlet. Steam specific entropy at the governing valve outlet is higher than steam specific entropy at valve inlet due to pressure reduction and losses which can occur during this process. Pressure reduction on the governing valve and specific entropy difference (increment) on the same governing valve are directly proportional - they increase during the decrease in steam system load, Fig. 5.

Fig. 5. Change of steam specific entropy increment between governing valve outlet and inlet during the change in system load

Specific entropy increment of any steam plant component represents losses which occur during the component operation and therefore, it can also be the real indicator of the analyzed component operation. When comparing Fig. 4 and Fig. 5 it can be concluded that calculation of exergy destruction is not necessary for governing valve loss assessment at different steam system loads - it is enough to calculate steam specific entropy increment. So, steam specific entropy increment can be used as a tool for quick assessment of valve losses, while a detailed analysis require calculation of valve exergy destruction.

From Fig. 5 it can be seen that analyzed valve specific entropy increment decreases with an increase in steam system load from 0.224 kJ/kg·K at 60% of load to 0.112 kJ/kg·K at 80% of load. At the highest load, valve specific entropy increment amounts only 0.021 kJ/kg·K.

5.2 Governing valve exergy analysis - the ambient temperature variation

As for the most other steam plant components [22], it can be expected that the influence of the ambient temperature change on exergy analysis of governing valve will also have low impact. In this analysis, the ambient temperature was varied from 283 K to 313 K in the steps of 10 K, while the ambient pressure remains constant at the measurement state (1 bar) in each observed system load.

The change in analyzed governing valve exergy destruction for all observed steam system loads during the ambient temperature variation is presented in Fig. 6. It can clearly be seen that the ambient temperature change has as higher impact on valve exergy destruction as the steam system load decreases.

At the highest steam system load, valve exergy destruction is the lowest and increase in the ambient temperature for 10 K causes a slight increase in valve exergy destruction for only 120 kW in average. The same increase in the ambient temperature resulted in an increase in valve exergy destruction for 500 kW in average at the steam system load of 80%. At the lowest steam system load of 60% increase in the ambient temperature for 10 K causes the highest increase in valve exergy destruction which is 740 kW in average.

Several conclusions can be derived from Fig. 6. First of all, governing valve exergy destruction (exergy power losses) significantly increases during the decrease in steam system load. Second, the change in the ambient temperature more and more affects the valve exergy destruction as steam system load decreases.

Fig. 6. Change of governing valve exergy destruction during the variation in the ambient temperature

Analyzed governing valve exergy efficiency change during the ambient temperature variation is presented in Table 2. The ambient temperature increase causes decrease in governing valve exergy efficiency, but that decrease is low at all steam system loads. Still, the highest decrease in governing valve exergy efficiency during the ambient temperature increase is notable at the lowest system load.
6. Conclusion

The paper presents exergy analysis of steam turbine governing valve mounted on the high pressure turbine inlet in a super critical thermal power plant. Governing valve was analyzed through three different steam system loads. Measurement results of steam operating parameters (pressures, temperatures and mass flow rates) at governing valve inlet and outlet enables calculation of valve exergy power inputs and outputs, as well as valve exergy destruction and exergy efficiency at each steam system load.

Increase in steam mass flow rate is the most important reason for the increase of valve exergy power input and output during the increase in steam system load. The difference between valve exergy power input and output becomes lower as steam system load increases. That difference represents valve exergy destruction (valve exergy power losses) at each steam system load.

The lowest valve exergy destruction which amounts 3598 kW and the highest valve exergy efficiency (99.57%) was obtained at the highest steam system load. Decrease in steam system load resulted in an increase in valve exergy destruction which is 13550 kW at 80% of load and 21360 kW at 60% of load, while at the same time valve exergy efficiency decreases (97.87% - 80% of load and 95.58% - 60% of load).

Steam specific entropy difference (increment) between valve outlet and inlet is an additional operating parameter which can be used for detecting the change in steam plant load. Steam specific entropy increment of the analyzed valve can also be used as a tool for quick assessment of valve losses.

The conclusion which follows from the ambient temperature variation is that the ambient temperature influence on analyzed governing valve exergy analysis is low, especially at the highest steam system load where the majority of valve operation can be expected.

1. Introduction

The adoption of the legal regulations for limiting the emissions of toxic components from the exhaust gases of internal combustion engines initiated many extensive examinations mainly in the interior of the engine and the additional treatment of exhaust gases through thermal and catalytic reactors, contributed to the reduction of toxic emissions.

The day-to-day development of internal combustion engines is aimed at reducing the toxic emissions of exhaust gases at the barrier level and reducing fuel consumption, while maintaining the good engine characteristics.

Environmental pollution is a permanent process and it is a complex phenomenon that is relatively slowly being explored and the legitimacy of these are completely not defined. For many occurrences, there are only hypotheses and assumptions, such as the warming of the atmosphere in global proportions.

The biological existence of a human is inextricably linked to the biosphere that is the main ecosystem of the country, which, with the help of natural self-regulatory processes, is in the state of dynamic equilibrium. Until the beginning of the rapid development of industrialization, urbanization and motorization, which took place in different countries at different times, it was considered that pure air and water were in unlimited quantities, and the pollution that occurred as a result of human activity was easily assimilated and removed, as a result of the great power of self-awareness of these media. Alongside with the increase in human activity in various spheres, the first signs of degradation of the environment.

The more the man wanted to change the environment, the more he burdened the country of the ball with various degradation problems, seeking the most urgent solution. The degradation of the environment gradually slowed down all over the environment in which the human being lives, so it is difficult to determine its dimensions and the consequences that it causes.

2. The efficiency of the internal combustion motors in the aggregate pollution of the atmosphere

Due to the huge economy, the favorable specific power and the favorable dimensions, the engines are accepted as the most suitable source of thermal mechanical energy in many areas of application. In road transport, they represent an exceptional means of propulsion.

With combustion of 1 (t) fuel in the engine, depending on the type of engine, the operating mode and regulation, can occur in the exhaust gases: 150 – 800 kg CO, 7.5 – 40 kg NOx and 30 – 100 kg CnHm.

The data for the participation of internal combustion engines as aeronautics are very diverse. These data are in some ways one of the main indicators for industrial development. In addition, the most developed countries are the largest aerospace producers.

Observing the impact of internal combustion engines as aeronautics, in Central Europe, was noted that their share in the CO emission is 65%, the NOx emission is 55%, CnHm is 40%, and the SO2 is 3%. The estimated impact of the main air pollutants in relation to the emissions of wastes in R. of North Macedonia for the end of the twentieth century is shown in the impact assessment. Table 2 shows that the largest part of all emissions originated from the combustion processes. The traffic is the largest emitter of carbon monoxide, hydrogen peroxide and nitrogen oxides. On the other hand, the largest part of the emitted sulfur originates from the stationary power stations of the electric power station and from the local and general consumption. This structure of issuers and emissions is also valid for other countries, depending on their degree of industrialization, urbanization and motorization.

Table 2. The estimated impact of the main air pollutants in relation to the emissions of wastes in R. of North Macedonia for the end of the twentieth century is shown in the impact assessment.

Keywords: norms, legal regulations, internal combustion engines, environmental criteria.
Engines with internal combustion, regardless of the degree of combustion, emit pollutants which pose a potential danger to the environment, while at the same time impairing the safety in traffic.

It was noted that when combining 1 l. petrol is obtained from about 10 (m3) gas. Out of the total produced amount of lead (which is about 2 million annual losses of about 50 thousand tons), about 10% is spent on antidecorator additives, which the exhaust gases are grounded in the environment.

The SO emission is most likely to emerge from the traffic and, for example, in the past 1982.

In terms of SO2 emission, industrial facilities have a far-reaching role, thermal power installations and the heaters (installations in which the fuel oil is oil and coal). From these pollutants it is assumed that SO2 plays, a decisive role in the creation of the so-called "acid rains" that destroy the plants across the length of the main roads in Europe.

The given data clearly indicate the gradual acceleration of the pollution of the atmosphere on the planet's surface. The distribution of the pollution is not uniform across the entire planet's surface, so the pollutant has recorded more pollution (93% of the total pollution) of the atmosphere relative to the southern hemisphere. This is due to the uneven development of the industry, because the developed industrial countries are located on the northern hemisphere. About 90% of these pollutants pollute 8 - 10% of the surface of the planet's surface (parts of Europe, North America and Japan), or 3% of the total surface of the planets.

On this basis, an orientation assessment can be given for the needs of the air for combustion of the planet's fuel. In 2000, they amount to 22.1012 (m3 / year), which is 0.01% of the total mass of the atmosphere.

For the calculation of the maximum terrestrial concentration of harmful substances from conventional fuels as sources of pollution, the known equation of Voeikov is used to calculate the maximum ground concentration from precise sources of pollution, where:

- A - coefficient of temperature stratification of the atmosphere, which depends on the meteorological conditions;
- \( E_{\mathrm{sp}} \) (g/s) – emissions of sulfur and nitrogen dioxide, or solid particles from all vehicles at the intersection;
- \( F_1 \) – without a dimensional coefficient that takes into account the speed of road charges, which depends on the level of clearance and in this case it can be taken \( F_1 = 3 \);
- \( \min \) – without dimensional coefficients which take into account the exhaust outlet conditions and are calculated according to the following expressions;

\[
m = \frac{1}{0.67 + 0.1\sqrt{f} + 0.34\sqrt[3]{f}}
\]

\( f \) – parameter that is calculated:

\[
f = \frac{10^4 W_g^2 d_i^2}{H_0^2 \Delta T} + \frac{27}{d_i^2}
\]

\( d_i (m) \) – the diameter of the exhaust pipe light;
\( w_g (m/s) \) – the speed of the combustion products of the exhaust pipe, which can be calculated according to the following level;

\[
W_g = \frac{\sqrt{\frac{V_g}{d_i^2}}}{H_0 (m/s)}
\]

To compile, to calculate the coefficient “\( n \)”, it is necessary to pre-calculate the \( V_m \) parameter:

\[
V_m = 0.65 \frac{\sqrt{\frac{V_g}{d_i^2}}}{H_0}
\]

at:

\[
V_m \leq 0.3 \quad n = 0.3
\]

\[
0.3 < V_m \leq 2.0
\]

\[
n = 3 - \sqrt{(V_m - 0.3)(4.35 - V_m)}
\]

\[
V_m \leq 2.0 \quad n = 1.0
\]

\( V_g (m^3/s) \) – volume flow of combustion products reduced to a condition that governs the exit of the exhaust pipe;

\( \Delta T = t_k - \text{tst} \) (°C) - the temperature difference between the temperatures of the products of combustion (exhaust gases) on the exit of the exhaust pipe and the medium temperature of the air.

The exhaust gas temperature of the exhaust pipe is different for vehicles with internal combustion \( t_{gE} \) and diesel motors \( t_{GD} \), so because of that in this case, work with medium temperature of the combustion products:

\[
t_g = \frac{t_{gE} + t_{GD}}{2} \quad ^\circ C
\]

An important magnitude that is penetrated in the calculation is the diameter of the adopted exhaust pipe which in this case is:

\[
d_a = n_e d_i^c
\]

\( n_e \) – number of vehicles at the intersection

\( d_i^c (m) \) - diameter of the exhaust pipe of one vehicle (equivalent vehicle).

The concentration of harmful substances in urban areas is influenced by several factors:

a) Influence of meteorological factors
   - Impact on the speed of air movement (wind);
   - Impact on the temperature of the outdoor air;
   - Impact on the direction of air movement (wind),

b) the impact of the factor taking into account the geographic position of the urban environment;

c) impact of the factors that depend on the thermal power plants in the urban environment.

\( \Pi \) (%) – percentage representation of vehicles with internal combustion and diesel engines (for internal combustion motors much more in relation to Diesel engines), at intersections,

\[
n_{ai} \rightarrow \text{total number of vehicles on the intersection}
\]

The volume flow of the combustion products (exhaust gases) under normal conditions is calculated according to the expression:
\[ V_{gi}^i = 0.2778 B_i n_i B_t \]  
\[ i = B, D \]

<table>

</tr>
<tr>
<td>n_i</td>
<td>– number of equivalent vehicles with internal combustion and diesel motors</td>
</tr>
</tbody>
</table>

The volume flow of combustion products is reduced to the conditions that the control of the exhaust pipe from the exhaust pipe is calculated according to the expression:

\[ t_g(°C) \] - temperature of the products of combustion of the exhaust from the exhaust pipe for the Otto or Diesel engine, which varies, but is usually less than 100 (°C). By measuring the \( t_g \) of several vehicles idling on the engine, the following values were obtained:

- for internal combustion motors, \( t_g = 70(°C) \) or 343 (K)
- for diesel motors, \( t_g = 60(°C) \) or 333 (K)

Measured temperatures are in accordance with the temperatures of the combustion products in the cylinder at the end of the extraction process, which move in the following borders:

- for internal combustion motors, \( t_p = 800 - 1100 \) (K)
- for diesel motors, \( t_p = 700 - 900 \) (K)

The total volume flow of the combustion products is the sum of the volume flows of the combustion products from internal combustion and diesel motor respectively:

\[ V_g = \sum V_{gi} = V_{gB} + V_{gD} (m^3/s) \]

CO₂ emission from vehicle with internal combustion or diesel motor is calculated with the following expression:

\[ E_{SO2} = 5.556 B_i S_i (1 - n_{SO2}) (1 - n_{SO2}) \]

B_i (t/h) – petrol or diesel fuel consumption

\( S_i \) (%) – content of petrol or diesel fuel

\( n_{SO2} \) – coefficient that takes into account the percentage of SO₂ retention in the exhaust part of the engine and runs for liquid fuels (petrol and diesel) within the limits (0,0 – 0,2)

\( n_{SO2} = 0 \) - a coefficient that takes into account the percentage of SO₂ in the purifier of solid particles and in the vehicle is zero at all under the condition that there is no purifier of the combustion products

The total SO₂ emission of all vehicles at the intersection is calculated according to the following expression:

\[ E_{SO2} = \sum n_i \sum i S_i = n_{eB} E_{SO2B} + n_{eD} E_{SO2D} (g/s) \]

\( n_{eB}, n_{eD} \) – number of vehicles with internal combustion or diesel motors at the intersection.

The NO₂ emission from the vehicle with the internal combustion and diesel engine is calculated according to the expression:

\[ D_{el} = \frac{4 k_e}{\pi} \] (m) – the equivalent diameter of the combustion area for internal combustion and diesel motor

\( A_{el} = \frac{A_{el}}{4} n_i \) (m²) – cross section of the cylinder for internal combustion and diesel motor

\( S_i \) – piston path for internal combustion and diesel motor

\( D_{el} \) – the diameter of the cylinder for internal combustion and diesel motor

For internal combustion motor, \( S_B = 1.1 \rightarrow 1.3 \)

\[ \frac{S_B}{D_{el}} = 0.8 \Rightarrow S_B = 0.8 D_{el} \]

For diesel motor, \( S_D = 1.3 \rightarrow 1.7 \)

\[ \frac{S_D}{D_{el}} = 1.3 \Rightarrow S_D = 1.3 D_{el} \]

\[ V_{gD} = \frac{\pi D^2}{4} \] 1.3\( D_{el} = 0.325\pi D^2 \)

\[ D_{el} = \frac{V_{gB}}{0.2 \pi} \] (cm)

\[ D_{el} = \frac{V_{gD}}{0.32 \pi} \] (cm)

We will get the values for \( V_{el} \) from the cylinder displacement:

\[ V_{el} = \frac{V_i}{n_{el}} (cm^3) \]

\( n_{el} \) – number of cylinders at internal combustion and diesel motors

The total NO₂ emissions from all vehicles at the intersection are calculated according to the following expression:

\[ E_{NO2} = \sum E_{el} = n_{eB} E_{NO2B} + n_{eD} E_{NO2D} \]

\( n_{eB}, n_{eD} \) – number of vehicles with internal combustion or diesel motors at the intersection.

The emission of solid particles from a vehicle with internal combustion or diesel engine is calculated according to the expression:

\[ E_{p} = 277.778 B_i \left[ 1 - \frac{U_4}{100} \right] A_4 g_{el} + \frac{U_4}{100} (g/s) \]

A_4 – ash content in petrol or diesel fuel

U_4, % - heat loss due to chemically incomplete combustion, in the vehicle with internal combustion or diesel engine that moves:

\[ U_4 = 0.5 \rightarrow 0.7 \]

\( g_{el} \) – part of the ash, which comes out with the products of combustion that the vehicles are carrying

\( g_{el} = 0 \rightarrow 0.1 \)

The total emission of solid particles from all vehicles at the intersection is calculated according to the following expression:

\[ E_p = \sum n_{el} E_{el} = n_{el} E_{el} + n_{elD} + E_{elD} (g/s) \]

\( n_{el}, n_{elD} \) – number of vehicles with internal combustion and diesel motors at the intersection.

The CO emissions from vehicles with internal combustion or diesel engine are calculated according to the expression:
Engines, they do not have a bright future ahead. Accordingly to the research of these especially in road transport, is internal combustion engines fueled gas, liquefied petroleum gas, water, etc. The total CO emissions from all vehicles on the intersection are calculated according to the expression:

\[ E_{\text{CO}} = \frac{12.5 U_4 H_d \beta_i' V_{\text{CO}_2}}{3.6(2354.4, 235 C_i' - U_4 H_d)} \text{ (g/s)} \]

Bi (t/h) – consumption of petrol i.e. diesel fuel

U4,(%) – heat loss due to chemically incomplete combustion, in the vehicle with internal combustion or diesel engine that moves:

\[ U_4 = 0.5 \rightarrow 0.7 \]

Hd, (kJ/kg) – lower thermal power on petrol or diesel fuel

\[ V_{\text{CO}_2} \] – volume of the CO2 combustion products at internal combustion and diesel motors

\[ V_{\text{CO}_2} = \frac{M_{\text{CO}_2}}{\rho \text{ CO}_2} \text{ (m³)} \]

\[ T_{\text{gb}} \] – temperature of the combustion products on the exit of the exhaust pipe for internal combustion and diesel motors, usually lower than 100°C.

- internal combustion motor \( T_{\text{gb}} = 70^\circ\text{C} = 343 \text{ K} \)
- diesel motor \( T_{\text{gb}} = 60^\circ\text{C} = 333 \text{ K} \)

\[ M_{\text{CO}_2} \] – weight of CO2 in combustion products

\[ \rho \text{ CO}_2 \] – density CO2 of in combustion products at petrol and diesel fuel

\[ \rho \text{ CO}_2 = \frac{100000}{1000 R_{\text{CO}_2}(T_{\text{gb}} + 273.5)} \text{ (kg/m³)} \]

\[ R_{\text{CO}_2} \] – gas constant for CO2 at internal combustion and diesel motor

3. Alternative fuels and their ecological qualities in relation to conventional fuels

Since it has been established that the utilized energy potential of the Earth has been completed, the term "energy crisis" is emerging. The energy crisis and knowledge of the limitations of natural reserves for the production of conventional fuels, gasoline and diesel fuel are increasingly given to them the significance of fuels that can be produced from raw materials that are available in practically unlimited quantities.

The total CO emissions from all vehicles on the intersection are calculated according to the expression:

\[ E_{\text{CO}} = \sum_i n_{e_i} F_{\text{CO}_i} = n_{e_2} F_{\text{CO}_2} + n_{e_3} F_{\text{CO}_3} \text{ (g/s)} \]

\[ n_{e_i} \] – number of vehicles with internal combustion and diesel motor.

- Methanol – one kind of alternative fuel

Methanol (methyl alcohol - CH₃OH) is a colorless, transparent, low-viscosity liquid characterized by an alcoholic scent. It is made of stone, coal, natural gas, purifier, organic waste or as a by-product in the organic - chemical industry. Physical – chemical characteristics of methanol, differ from commonly used fuels and have a significant impact on the course of combustion and emission of exhaust gases.

The following conclusions are important:

- Viscosity, density, as well as the heat in the mixture of petrol and methanol, differ significantly.
- The presence of chemical oxygen in the alcohols reduces the heat of combustion. That's why methanol has an enlarged specific consumption.
- The optimum pre-ignition angle of the engine with methanol is less often used when working with gasoline, which indicates a change in the combustion engine, the second and the faster progress of the combustion process.
- The effective degree of usefulness - when working with methanol is higher because of the low heat losses and the lower exhaust gas temperature.
- Methanol has a higher octane number, which is the reason for increasing the compression ratio \( e = 12 \div 14 \): 1, and thus increasing the effective power of the engine.
- When working with methanol, the limits of the flammability of the mixture, especially in the context of its impotence, are being sprayed.
- In the field of rich mixture in (\( \lambda \leq 1 \)) when working with methanol, the CO is significantly reduced in the exhaust gases.
- Methanol showed favorable emissions of uncombusted gases. The methanol drive showed a favorable emissions of both carbon dioxide CH, in the whole field of interest in the high-air coefficient. The values of the total quantities of undamaged hydrocarbons shown in the diagram are measured using a flame ionizing FID analyzer. Measured on FID - Regulations showed confidence in the analysis of the products of combustion. The sensitivity of FID alcohol analyzers is considerably smaller than the usual components contained in normal fuels: paraffins, olefins and aromatics. In this way, a large part of the combusted hydrocarbons can not be registered with the current common method of measurement.
- The environmental indicators of the engine while working on methanol are virtually identical and significantly improved as they work on gasoline. The low pressure of the saturated steam of the methanol impairs the initial engine qualities, as it will be necessary to add to the wood-volatile hydrocarbons. In winter conditions, electric heating is necessary.
- Methanol mixing in any proportion with water is successful, but the mixture of methanol and water causes corrosion of the engine parts.
- The disadvantage of methanol as motor fuel is that there is a large amount of aldehydes in the exhaust gases.
- Methanol vapors are often more harmful to human health than petrol’s.

An interesting variant of the drive is the operation of the internal combustion engine with a mixture of gasoline and methanol. The conversion of 20% methanol in the fuel is achieved, without any changes in the engine, the oscillation of the mixture by 8.8% and that is so called M20 fuel. In this way, the composition of the exhaust gases is significantly
improved. Such a reduction was achieved by 75% SO, 30% for HC and 22% for NO. Secondary problems are not recorded.

Conclusion

The day-to-day development of internal combustion engines is aimed at reducing the toxic emissions of exhaust gases at the barrier level and reducing fuel consumption, while maintaining the good engine characteristics.

Engines with internal combustion, regardless of the degree of combustion, emitted emissions which pose a potential danger to the environment, while at the same time impairing the safety in traffic.

Resolving environmental problems leads to research focused on the selection of appropriate fuel as an alternative fuel, which would be a worthwhile replacement of the used white derivatives – gasoline and diesel fuel for internal combustion engines.

Methanol is one kind of alternative fuel that is alternative to existing fuels, it is a colorless, transparent, low-viscosity liquid characterized by an alcoholic scent. The effective degree of usefulness - when working with methanol is higher because of the low heat losses and the lower exhaust gas temperature.

Methanol and other alternative fuels will be the new fuels which are going to be use for motors with internal combustion.

Alternative fuels are healthier for the environment, cheaper for the consumers and with better combustion than standard fuels.

OBJECTIFICATION AND DETERMINATION OF HAND-ARMD VIBRATIONS

doc. Ing. Michaela Balážiková, PhD. 1, doc. Ing. Marianna Tomašková, PhD. 1
Technical University of Kosice, Letná 9, 042 00 Kosice, Slovakia, Faculty of Mechanical Engineering, Department of Safety and Quality, Kosice, Slovakia Republic 1
michaela.balazikova@tuke.sk, marianna.tomaskova@tuke.sk

Abstract: The paper is devoted to objectification and determination of the influence of hand-arm vibrations with selected machinery. We permanently meet with vibrations, but especially when performing work activities. When working with machinery, a person is constantly exposed to vibrations and they can very negatively affect the health of the person. The aim of the paper is to compare measured vibration values with the manual of the device and then to determine the maximum time exposure for work activities to avoid the employee being at risk of working with the device. Comparison of a final hand-arm vibration will be assessed by means of the hand-arm exposure calculator and software for a specific measuring device - vibration analyzer of the 4447 type. The proposed method - an extended risk matrix - is used to assess the risks of hand-arm vibration.

Keywords: VIBRATIONS, SAFETY, OCCUPATIONAL HEALTH PROTECTION

1. Introduction

Many work activities require regular and frequent use of vibrating tools and equipment. The handling of vibrating materials is also widely found in industries and provision of services. It is, for example, civil engineering, building of roads and railways, maintenance and improvement of real estate (maintenance of terrain, parks, watercourses, roads and their adjacent green belts), production of concrete products, forestry, foundry, heavy engineering, mining and surface mining - production and repair of automobiles, supply services to the public (works for water water management companies, gas companies, power plants and telecommunication companies), building and repair of ships and other.

When in contact with work equipment and mechanical tools, a person is often exposed to shocks and vibrations that are harmful to human health when exceeding certain values. Vibrations increase the fatigue of a person because a large amount of muscle is trying to capture their effects. Damages caused by vibrations are dependent on amplitude, frequency, acceleration, and vibration count. They are caused in particular by chainsaws, drills, pneumatic hammers - locally transmitted vibrations (hand-arm vibrations), vibrating machines where the worker is sitting or standing - tractors, mobile machines - whole body vibration, special transmission - carried on the back. (OSHA, 2011)

2. Health risks associated with hand-arm vibration exposure

Some hand tools produce high vibration acceleration levels that can cause permanent damage to the hands and arms. This risk is caused by the Hand-Arm Vibration Syndrome (HAVS) syndrome which depends on the following factors:
- position and method of gripping tools,
- the length of time interval of work activity with tools,
- heat and cold load in the working environment,
- vibration level.

Exposure to hand-arm vibration syndrome could cause serious health-damaging effects, circulatory disorders, such as vibration white finger (VWF), sensitivity of the senses impairment, muscle, bone and joint damage. The second and more serious manifestation of the disease is the so-called Raynaud’s syndrome, vibration white finger disease may occur at frequencies between 5-2,000 Hz, but the greatest risk is between 5-150 Hz. (OSHA, 2011)

3. Legal framework of the European Union related to factors at work

Measurement, objectification, and assessment of vibrations must firstly be in line with the applicable procedures and proposals that are underpinned by relevant valid binding legislation. The main legislative aspects used for the measurement and assessment of hand-arm vibrations for which the different methods of exposure determination are as follows:

This legislation sets out the limit and action values of vibration that can not be exceeded during the work performed. It contains methods for measuring and calculating the normalized vibration acceleration by means of which representative vibration values are obtained and then compared with the permissible values. This will also include assignment to the appropriate category of work. Table 1 lists the respective action and limit values of hand-arm vibrations. (Directive 2002/44/EEC)

4. Material and methods

Risk assessment procedure according to “Non-binding guide to good practice with a view of implementation of Directive 2002/44/EC (Vibrations at Work) issued by the European Commission (EC) in 2009 is described in detail below.

The factors that govern the daily exposure of a person to vibrations are the frequency weighted vibration force (level) and the time of exposure of the person to this vibrational force. The greater the force is or the longer the exposure lasts, the greater the exposure of the person to the vibrations is.

The whole process can be modeled on the example of manual grinding of metallic material - performed irregularly during the work shift - profession of a locksmith. To assess the threat rate, a representative sample value of 75% of the instruments was selected, i.e., acceleration
The estimation of daily vibration exposure $A(8)$ can be based on observation based on real work activities undertaken, i.e., on maximum length of exposure to vibrations transmitted to the worker’s hand and arm (Hand-arm vibration exposure calculator, 2012), for example:

- grinding and cutting with an electric angle grinder with maximum duration 1 hour and duration 10 min.

Using the daily exposure estimation diagram $A(8)$ - Fig. 1, it is possible to determine the values for grinding and cutting on the apparatus under consideration, i.e.:

- grinding ($7 \text{ m/s}^2$ per 60 min.): $A(8) = 2.5 \text{ m/s}^2$
- cutting ($7 \text{ m/s}^2$ per 10 min.): $A(8) = 0.5 \text{ m/s}^2$

Total exposure to vibration will be evaluated by relationship:

$$A(8) = (A1(8)^2 + A2(8)^2)^{1/2}$$

i.e. after entering

$$A(8) = (2.5^2 + 0.5^2)^{1/2} = (6.25 + 0.25)^{1/2} = 2.55 \text{ m/s}^2$$

When comparing graph limits, this calculated value of the total vibration exposure resulting from the activity under consideration is just above the action value of $2.55 \text{ m/s}^2$, i.e., still within an acceptable range but indicating the need for taking measures.

Vibrations were measured on three selected devices that were used in selected work activities where measured vibrations were evaluated and it was determined whether the values were exceeded according to the standard and according to the relevant operating instructions being a part of each device.

Vibration values (measured and values mentioned in the operating instructions) were compared and analyzed by the following methods:

- by software that is a part of the 4447 vibration analyzer,
- by freely available hand-arm vibration evaluation calculator developed by the Health and Safety Executive (HSE), also subject to Directive 2002/44/EEC.

**Measurement No. 1: Jigsaw**

The jigsaw is used to cut wood. With special knives, it is also possible to cut steel, plastic or aluminum.

Specifications of the jigsaw are recorded in Table 2.

**Table 2: Specifications of the device – jigsaw**

<table>
<thead>
<tr>
<th>Performance</th>
<th>Number of strokes</th>
<th>Length of stroke</th>
<th>Inclined position</th>
<th>Weight</th>

</thead>
<tbody>
<tr>
<td>550 W</td>
<td>31 000/min</td>
<td>26 mm</td>
<td>45° on both sides</td>
<td>2.4 kg</td>
</tr>
</tbody>
</table>

Table 3 shows the values recorded in the manuals as well as the values obtained by measuring the vibrations by the analyzer from the device during activity - wood cutting.

**Table 3: Vibration values in manuals and vibration analyzer 4447 - jigsaw**

<table>
<thead>
<tr>
<th>Activity</th>
<th>Vibration value in the device manuals</th>
<th>Vibration value measured by vibration analyzer 4447 at time exposures</th>
</tr>
</thead>
<tbody>
<tr>
<td>Wood cutting</td>
<td>$7.0 \text{ m/s}^2$</td>
<td>$0.741 \text{ m/s}^2$</td>
</tr>
<tr>
<td></td>
<td>$1.482 \text{ m/s}^2$</td>
<td>$2.096 \text{ m/s}^2$</td>
</tr>
</tbody>
</table>

Vibration measurement on the machinery was performed using vibration analyzer 4447 according to ISO 5349-1: 2001 (ISO 5349-1:2001). The vibration sensor was located on the device’s handle. By means of the device, sawing of 2 cm thick wood was carried out. (ISO 5349-2: 2001).

During measurement of vibrations, the limit and action values of vibrations were not exceeded. The measured vibration values obtained from the vibration analyzer match with the HSE hand-arm vibration exposure calculation for evaluation of the hand-arm vibration. Values from activities performed by means of the machine device at time exposure $A(1)$, i.e., $0.714 \text{ m/s}^2$ and even $A(4)$, i.e. $1.482 \text{ m/s}^2$ were minimum and did not exceed the set and allowed values. Measured vibration values at 8 hour exposure were $2.096 \text{ m/s}^2$. With this machine device it is possible to work 8 hours or more because the vibrations should not be exceeded.

By means of the HSE hand-arm vibration exposure calculator, it is possible to compare and find out whether the values in the exposures fall within and do not exceed the action and limit value of vibrations, and also determine how long it is possible to work with the machine in order not to exceed the action and limit values. In this case, on the HSE Calculator (EC Handbook, 2009) (Fig. 2), that the values with this device are not exceeded and meet the action and limit values of the vibrations for a given time exposure. From the measured values, it has been found that with this device, it is possible to work without problems even 8 hours or more.

According to the value mentioned in the operating instructions, it is possible to work with the work equipment for only 1 hour and 1 minute so that the accelerating action is not exceeded and 4 hours and 5 minutes in order not to exceed the limit value.

The rate of acceptability of the risk of exposure to vibrations:

- $A(8) < 2.5 \text{ m/s}^2$. The daily exposure to vibrations is lower than the level during activity. There is no need to take special measures to reduce exposure.
- $A(8) = 2.5 - 5.0 \text{ m/s}^2$. Daily vibration exceeds the level during level. For users, there is an increased risk of the disease caused by vibrations. Apply the manufacturer's recommendations and the measures mentioned in Directive 2002/44 / EC to reduce the risk of mechanical vibration.
- $A(8) > 5.0 \text{ m/s}^2$. Daily exposure to vibration exceeds the exposure limit values. Shorten your daily working time or use a machine with a lower equivalent vibration level.

The analyse and evaluate, the type 4447 hand-arm vibration analyzer also includes appropriate software. A vibration sensor and apparatus that is attached to it measures the vibrations stored in the analyzer and can be transmitted to the computer and evaluated using the software. The software evaluates and shows how many hours a person can work with the device to avoid vibration values being exceeded when operating with the device. (B&K)

**5. Analysis and experiment evaluation**

The aim of the experimental measurement was to assess whether the indicated values of the transmission of vibration to the hand and arm in the operating instructions comply with the legislative requirements of Directive 2002/44/EEC. The hand-arm vibration transmission measurement was performed using a 4447 vibration analyzer. The instrument meets the technical requirements of EN ISO 8041 and allows measurement according to the following standards:

- ISO 5349 Hand-arm vibrations,
- ISO 2631 Whole-body vibrations.

The vibration measurement on the jigsaw machine was performed using vibration analyzer 4447 according to ISO 5349-1: 2001 (ISO 5349-1:2001). The vibration sensor was located on the device’s handle. By means of the device, sawing of 2 cm thick wood was carried out. (ISO 5349-2: 2001).

During measurement of vibrations, the limit and action values of vibrations were not exceeded. The measured vibration values obtained from the vibration analyzer match with the HSE hand-arm vibration exposure calculation for evaluation of the hand-arm vibration. Values from activities performed by means of the machine device at time exposure $A(1)$, i.e., $0.714 \text{ m/s}^2$ and even $A(4)$, i.e. $1.482 \text{ m/s}^2$ were minimum and did not exceed the set and allowed values. Measured vibration values at 8 hour exposure were $2.096 \text{ m/s}^2$. With this machine device it is possible to work 8 hours or more because the vibrations should not be exceeded.

By means of the HSE hand-arm vibration exposure calculator, it is possible to compare and find out whether the values in the exposures fall within and do not exceed the action and limit value of vibrations, and also determine how long it is possible to work with the machine in order not to exceed the action and limit values. In this case, on the HSE Calculator (EC Handbook, 2009) (Fig. 2), that the values with this device are not exceeded and meet the action and limit values of the vibrations for a given time exposure. From the measured values, it has been found that with this device, it is possible to work without problems even 8 hours or more.

According to the value mentioned in the operating instructions, it is possible to work with the work equipment for only 1 hour and 1 minute so that the accelerating action is not exceeded and 4 hours and 5 minutes in order not to exceed the limit value.
Measurement No.2: Angle grinder

This device is designed for cutting, planing metal or even stone materials without the need for water. A special protection cover can also be used when cutting. This machine can also be used for grinding with grinding paper. The device specifications can be found in Table 4.

Table 4: Specifications of the device – angle grinder

<table>
<thead>
<tr>
<th>Weight</th>
<th>Maximum diameter of grinding disc</th>
<th>Rated power input</th>
<th>Rated rpm</th>
</tr>
</thead>
<tbody>
<tr>
<td>1.7 kg</td>
<td>115 mm</td>
<td>701 W</td>
<td>11 000 min⁻¹</td>
</tr>
</tbody>
</table>

The vibrations on this machine were measured with a vibration analyzer using a tri-axis sensor. Vibration measurement on the device was done during iron grinding.

Table 5: Vibration values in manuals and vibration analyzer 4447 when grinding with an angle grinder

<table>
<thead>
<tr>
<th>Activity</th>
<th>Vibration value in the device manual</th>
<th>Vibration value measured by vibration analyzer 4447 at time exposures</th>
</tr>
</thead>
<tbody>
<tr>
<td>Iron grinding</td>
<td>8.0 m/s²</td>
<td>1.459 m/s² 2.918 m/s² 4.127 m/s²</td>
</tr>
</tbody>
</table>

The measured vibration value at exposure of 1 hour A(1) was 1.459 m/s². The vibration value at exposure of 4 hours A(4) was 2.918 m/s², which means that the vibration action value, which is 2.5 m / s², was exceeded.

Upon these values, it can be stated that the worker can work with this device for 2 hours and 56 minutes to avoid exceeding the values.

At the vibration value measured for the 8 hour A(8) time exposure is 4.127 m/s² which exceeds the action value.

We obtained the measured vibration by means of a hand vibration analyzer 4447 on the machinery, i.e., an impact drill.

Table 7: Vibration values in a handbook and according to vibration analyzer 4447 for drilling in wood with impact

<table>
<thead>
<tr>
<th>Activity</th>
<th>Vibration value in the device manual</th>
<th>Vibration value measured by vibration analyzer 4447 at time exposures</th>
</tr>
</thead>
<tbody>
<tr>
<td>Drilling in wood with the impact</td>
<td>25.3 m/s²</td>
<td>1.673 m/s² 3.347 m/s² 4.734 m/s²</td>
</tr>
</tbody>
</table>

The value of vibrations at an hour work A(1) was measured as 1.673 m/s². The value did not exceed either the action or limit value.

The value of four-hour A(4) vibrations was 3.347 m/s², and the worker can only work 2 hours and 13 minutes at this value to avoid exceeding the values according to the standard.

At work lasting eight hours A(8), the value of vibrations was 4.734 m/s², exceeding the limit value.

The measured data in the above mentioned three time exposures can be reassessed using the HSE hand-arm vibration calculator. According to the calculator, the employee can work for 8 hours without exceeding the HSE limit value (Handbook EC, 2009), Fig.4.

Suggestion of a method for estimation of a risk of hand-arm vibration

For management of risk of vibration transmission, by harmonizing the risks of exposure to vibrations, it is possible to apply a standard matrix of risks, e.g. with use of parameters of period of exposure E (duration of exposure), probability of health hazard caused by exposure to vibrations resulting from work activities P and impacts D, see the Tab. 8. (Pačiaová, 2014)
Impact vibration may occur in these cases even if the time exposure is not operating instructions applies. Damage to the upper limbs due to well as with an impact drill if the vibration value mentioned in the operating instructions were recalculated to show how long it is possible to work with the equipment in question so that the high risk is in the case of working with an angle grinder as than those mentioned in the operating instruction for the device when calculated with the values mentioned in the operating instructions. Based on the results, it can be stated that the measured values are much lower than those mentioned in the operating instruction for the device. According to the measured values, the vibration action values would be exceeded only in case of working with an impact drill so it is possible to work with this device max. 4 hours to avoid health damage.

The proposed method, based on Directive 89/391/EEC, was also used to assess the risk of hand-arm vibration. (Directive 89/391/EEC) Based on the assessment, it is possible to conclude that the high risk is in the case of working with an angle grinder as well as with an impact drill if the vibration value mentioned in the operating instructions applies. Damage to the upper limbs due to vibration may occur in these cases even if the time exposure is not exceeded.

### Table 8: Suggestion of a method for estimation of risk of hand-arm vibrations (Pačaiová, 2014)

<table>
<thead>
<tr>
<th>Impact (D)</th>
<th>Risk value (E+P) x D</th>
<th>Risk management</th>
</tr>
</thead>

</tbody>
</table>

Table 9 shows the vibration values mentioned in the operating instructions as well as the vibration values measured by the vibration analyzer. At recalculating to an 8-hour exposure, a freely available HSE calculator was used. The values mentioned in the operating instructions were recalculated to show how long it is possible to work with the equipment in question so that the vibration action or limit values given in the applicable legislation are not exceeded. Subsequently, the table in the third column shows the longest possible exposure with the device when calculated with the values mentioned in the operating instructions. Based on the results, it can be stated that the measured values are much lower than those mentioned in the operating instruction for the device. According to the measured values, the vibration action values would be exceeded only in case of working with an impact drill so it is possible to work with this device max. 4 hours to avoid health damage.

The proposed method, based on Directive 89/391/EEC, was also used to assess the risk of hand-arm vibration. (Directive 89/391/EEC) Based on the assessment, it is possible to conclude that the high risk is in the case of working with an angle grinder as well as with an impact drill if the vibration value mentioned in the operating instructions applies. Damage to the upper limbs due to vibration may occur in these cases even if the time exposure is not exceeded.

### Table 9: Application of the method for estimating the risk of the hand-arm vibration

### Conclusion

There are several recommendations for minimizing the harmful effects of vibration on the hand-arm system, while effectively combining them according to the type of work:
- replacing hand tools with a type that has a lower vibration level, allowing rest breaks, work device cycling, wearing warm gloves when working in cold environments or anti-vibration gloves, regular tool maintenance, training staff not to hold hand tools too firmly, advise workers to increase blood flow through repeated hand and finger exercises, education of workers and foremen regarding vibration hazard and encouraging them to report signals and symptoms of hand-arm vibration syndrome (HAVS).

According to the first recommendation, the use of tools with reduced vibrations is the appropriate measure. The problem of excessive vibration is widespread in most industrial plants using hand tools and tools. Excessive vibration interferes to a great extent with the working and living environment of the human being, thus affecting his/her health, physical and mental well-being. Legislation could also be more aware that by targeting vibration exposed workplaces and by thoroughly training workers using hand tools and tools during their working change, many negative effects of excessive vibration would be avoided.

An article was elaborated within VEGA 1/0121/18 Development of methods for implementing and verifying a comprehensive security solution in Smart Factory as part of Industry Strategy 4.0

FEATURES OF HYBRID ELECTRIC VEHICLE (HEV) TRANSMISSION

Post-graduate student Tonkov G.
Department of Transport Equipment, Todor Kableshkov University of Transport
Geo Milev str. 158, 1574 Sofia, Bulgaria
tonkov.smolyan@gmail.com

Abstract: The transmissions of HEVs or so-called hybrid transmissions (HT) are essentially power split transmissions, which almost always require planetary gears to split or sum up power. An essential prerequisite for reading and studying hybrid transmissions is the knowledge of planetary gear function and calculation. For example, the Toyota hybrid system can only be clarified using the principles of the planetary mechanism. In addition to Toyota’s decision, there are two modes of transmission (BMW, Daimler and GM) and many patent applications with similar ideas.

Technically speaking, these solutions are power split transmissions that turn into a hybrid system by adding an electric motor (EM), a generator (G) and an electric storage battery (SB). These transmissions perform the functions required for vehicles with an internal combustion engine, such as the HEV. These functions are launching, torque and speed conversion, reverse gear, and rapid gear-shifts in ascending or descending order. In addition, the requirements for HT are realized with the help of electronic control. For parallel HEV, a conventional gearbox plus EM is used. The automatic transmissions used in the mixed HEVs are designed with planetary gearboxes and are also known as automatic HTs. This article discusses the features of planetary gearboxes used in HEVs transmissions.

Keywords: HEV, TRANSMISSION, FEATURES

Introduction

Almost all today’s automatic transmissions use planetary gears for torque conversion. Depending on the switching device of individual planetary gears, both multi-disc brakes and multi-disc clutches [1,2,3,4] are used.

There is another application for planetary gearboxes, suitable for distribution of the power flow in HEV. Here, the possibility of torque distribution and, in the case of HEV speed control, is used in two branches - the internal combustion engine (ICE) and the electric motor/generator (MG).

This allows to improve the efficiency of transmission components, which may be mechanical, hydrostatic, hydrodynamic or electrical. Such systems are increasingly being used today. Thus, this application can be found in hybrid drives and stepless hydrostatic gearboxes. Planetary gearboxes are flexible and suitable, especially for power transmission gearboxes, because in this case they are a central component.

Features of an 8-speed gearbox for a hybrid electric vehicle

In order to better understand the characteristics of the HEV gearboxes, the example of the 8-speed automatic transmission ZF (Zahnradfabrik Friedrichshafen) [1,5] was used. This product can be fitted as a “classic automatic transmission” (8 hp) as well as a hybrid solution (8P). Several combinations can be selected. Figure 1 shows an embodiment as a hybrid transmission.

Fig. 1. Hybrid transmission box 8p70h from ZF [1]

With four planar rows and five friction elements, eight forward gears and one rear gear are formed. This new structure is developed using computer programs that create and compare all possible connectivity options. Appropriate criteria, such as speed and torque adjustments, determine variants for gear shifting.

A very large number of bindings must be examined, so only with powerful computer systems. Top software products such as CATIA V5, which is a leading product for almost all industrial enterprises [6], and the high-end PTC Creo software development software [9] apply. This includes design offices performing specialized activities such as tolerance analysis, specialized strength calculations and so on. [7]. Strong analysis and assessment of the load and the dangerous sections and sections is a final stage and a verification of the design results [8].

This gear box is a base for a series of power ranging from 140-300 kW and inputs from 300-1000 Nm with four planned dimensions. The design of automatic transmissions for HEV depends on the drive structure. In these cases, the hydrodynamic torque transformer is no longer needed and in this transmission the multi-disc oil clutch is offered as a source element in a neutral way. It is also possible to install an MG to start the ICE and also transmit power at parallel HEV between the ICE and the mechanical transmission. The all-wheel drive variant is part of the scope of the program in these transmissions, as the share of all-wheel drive vehicles is growing among the more powerful HEVs.

Figure 2 shows a sectional view of this gearbox with all indications. The brakes A and B, the clutches C, D and E and the planet rows 1 to 4 are respectively indicated. Instead of the hydrodynamic component, it is possible to integrate a multi-disc clutch into an oil tank or, in a hybrid construction, to place the MG in the existing installation space. This has the advantage that the manufacturer has virtually no installation problems, as the hybrid version is almost identical to the standard transmission.

Fig.2. A section of the 8-speed automatic transmission for HEV [1]
Transmission technology requires an additional electric oil pump. It is located parallel to the oil pump with mechanical drive. The reason is that MG generates HEV zero torque (idle) and the transmission has to drive the corresponding shifting gears. This is advantageous for increasing the moment when starting in MG mode.

The scheme of this automatic gearbox is shown in Figure 3.

![Fig.3. ZF schematic 8-speed automatic transmission for HEV [1]](image)

Using the scheme according to FIG. 3, a Wolf diagram is produced (Fig. 4) and the number of teeth is entered.

![Fig.4. Wolf ZF scheme for 8-speed automatic transmission for HEV [1]](image)

The first gear (Fig. 5) is almost classic with the brakes A and B and clutch C. The sun wheel on the fourth row is connected to the clutch C. The advantage of this switching is about 2.5 times less torque input the transmission for the brake B at a total gear ratio of 4.7.

1st gear: brakes A and B clutch C are engaged

\[ i_1 = \left| -\frac{4.7}{1} \right| = 4.7 \]

![Fig.5. ZF 8-speed automatic transmission for HEV - first gear [1]](image)

The second gear is also formed by the brakes A and B, now the clutch E is engaged and the ring wheel of the second row is connected to the sun wheel the fourth row (Fig. 6).

2nd gear brakes A and B and clutch E are engaged

\[ i_2 = \left| -\frac{9.39}{3} \right| = 3.13 \]

![Fig.6. ZF 8-speed automatic transmission for HEV - second gear [1]](image)

In the third gear, brake A is off and clutch C is on. This leads to a connecting shaft between the two sun wheels on the 1st and 2nd planet rows. To offset the torque (-2) of the ring wheel of the second row, the difference must be supplemented by the torque of the engine to the sun wheel of the last row (+0.81) (Figure 7).

3rd gear brake B and clutches C and E are engaged

\[ i_3 = \left| -\frac{3.81}{3-1.18} \right| = 2.104 \]

![Fig.7. ZF 8-speed automatic transmission for HEV - third gear [1]](image)

Determining the fourth gear with brake B and D and E is a bit more difficult. Helping to know is the ratio of torque of the sun and ring wheel of third row. This can be done by means of the clutch shaft between the sun wheel of the first row and the ring wheel of the second row. The fourth row determines the factor x, and hence the moment of the arm on the third planet row (Figure 8).

The 4th gear brake B and the D and E clutches are engaged

\[ i_4 = \left| -\frac{4.998}{3} \right| = 1.667 \]

![Fig.8. ZF 8-speed automatic transmission for HEV - fourth gear [1]](image)

The fifth gear is formed by changing the clutches E and C. The clutch C is switched on and the clutch E is off. All planet rows are involved in this gear. In addition to the second planet row torque, the engine must also maintain the torque applied to the clutch shaft between the third row ring wheel and the fourth row sun wheel via clutch C (Fig. 9).
5th gear brake B and clutches C and D are engaged

\[ i_5 = \left| \frac{-9,027}{7,029} \right| = 1,284 \]

Fig. 9. ZF 8-speed automatic transmission for HEV - fifth gear [1]

The sixth gear is the result of clutch E engaged and brake B disengaged. Now all the clutches are engaged and a direct gear with a ratio of \( i_6 = 1 \) is obtained. In this case, the third planet row operates, with the clutches C and D, transmitting the full torque of the engine. Clutch E must absorb the proportional torque from the sun wheel (on a third planet row). This is 38.3% of the input torque (Figure 10).

The 6th gear clutches C, D and E are engaged

\[ i_6 = \left| \frac{-1}{1} \right| = 1 \]

Fig. 10. ZF 8-speed automatic transmission for HEV - sixth gear [1]

By disengaging the clutch E and engaging the brake A, the seventh gear is obtained. Only second and third planet rows are used to make this gear. Only the division of incoming torque through the fixed connection (guided on 2nd and 3rd planar row) and the clutch C (Fig. 11) should be taken into account here.

7th gear brake A and clutches C and D are engaged

\[ i_7 = \left| \frac{-5,217}{6,217} \right| = 0,839 \]

Fig. 11. ZF 8-speed automatic transmission for HEV - seventh gear [1]

The eighth and thus "fastest" driving speed is the result of the switching of the clutches C and E, where C is disengaged and E is engaged. In place of clutch C, clutch D is engaged. Like the fourth gear, the clutch shaft between the second row sun wheel and the third row sun wheel is critical. Since the relation between the sun and ring wheels of the 3rd planet row is, the factor x and the output torque can be determined (Figure 12).

8th gear brake A and clutches D and E are on

\[ i_8 = \left| \frac{-2}{3} \right| = 0,667 \]

Fig. 12. ZF 8-speed automatic transmission for HEV - eighth gear [1]

The required reverse gear - with the reversal of the direction of rotation in the same direction of torque transmission - is formed by both the brakes A and B and the clutch D. Starting from the drive on the second planet row, respectively, the third and fourth planet row perform the reverse gear (Figure 13).

R gear brakes A and B and clutch D engaged

\[ i_R = \left| \frac{+9,891}{3} \right| = 3,297 \]

Fig. 13. ZF 8-speed automatic transmission for HEV - reverse gear [1]

The diagram in Fig. 14 shows the variants of ZF 8-speed automatic transmission for HEV.

As shown in Figure 14, there are eight harmonic stepped ratios that make sense for the modern vehicle transmission. The condition that a switching element is always switched off and another is switched on in ascending order with one gear is clearly visible in this diagram. In principle, three of the five switching elements are always included, and therefore only two elements are always excluded.
Conclusion

The mention above certainly has advantages in reducing unavoidable idle losses. Together with this very “clever” clutch structure and extended oil spreading, a 6% saving potential is achieved compared to the 6-speed automatic transmission, this 8-speed automatic transmission is no more severe than the 6-speed automatic transmission. With this product, the number of planetary rows and XPS planetary gearbox sizes will continue to grow. In addition to this ZF product, an eight-speed Aisin gearbox has been developed and Daimler AG already has a 9-speed automatic transmission in its program. The management of these planetary gearboxes is inextricably linked to actuators, which are essentially electromagnetic devices [10] activated by the HEV electronic control unit.

LITERATURE

A RESEARCH INTO THE EFFECT OF ATMOSPHERIC TURBULENCE ON THE MOTION OF A QUADROCOPTER WITH PID CONTROL

M.Sc. Kambushev M. PhD.¹
Faculty of Aviation, Dolna Mitropolia – National Military University, Veliko Turnovo, Bulgaria ¹

m_kambushev@yahoo.com

Abstract: This report looks at Dryden’s atmospheric turbulence model. Applying the turbulent model to the motion of a quadrocopter with PID control. Analysis of the impact of atmospheric disturbances on a quadrocopter flight.

Keywords: DRYDEN, ATMOSPHERIC TURBULENCE, QUADROCOPTER, PID CONTROL

1. Introduction

All types of aircraft are influenced by atmospheric turbulence and air currents. Depending on the size, type and height of the flight, atmospheric disturbances influence them differently. [5, 6]. One and the same disturbance, acting on an unmanned airplane flying high altitude [2], for example UAV Predator, and on the quadrocopter [4] flying several meters above the ground, will have little or no impact on flight parameters in the first case, and from there on the proper performance of the task, while in the case of the quadrocopter it can lead to a collision with the ground or a nearby obstacle (a building, a tree, etc.)[1]. This requires modeling and research of the quadrocopter movement, using different control methods in the presence of atmospheric disturbances.

In modeling the atmosphere, the most widely distributed model is the International Standard Atmosphere [8].

The reason for the occurrence of air currents is the uneven distribution of air pressure in the atmosphere. Depending on the season, the place above the ground, the relief of the area and the presence of vapors in the atmosphere, the air is heated differently by the sun. What is more, significant differences in temperature between the different layers in the horizontal and vertical directions appear resulting in a change in the density and pressure. Therefore, the solar-transmitted thermal energy is transformed into movement of air particles. They move at different speeds in different directions. If the particle speed exceeds a certain limit, the motion becomes turbulent. Such movement is of a random nature and is accompanied by significant vortices forming.Amathematical model of a real class 500 quadrocopter was made consisting of the following equations.

3. Modeling of quadrocopter flight with PID control in turbulent environment.

A mathematical model of a real class 500 quadrocopter was made consisting of the following equations.

\[ S_v(\Omega) = \frac{\sigma^2}{\pi} \frac{2L}{\Omega^2} \left( \frac{1}{1+\left(\frac{\Omega}{L}\right)^2} \right) ; \]
\[ S_h(\Omega) = \frac{\sigma^2}{\pi} \frac{2L_v}{\Omega^2} \left( \frac{1+12\left(\frac{\Omega}{L_v}\right)^2}{1+4\left(\Omega^2\Omega_v^2\right)^2} \right) ; \]
\[ S_w(\Omega) = \frac{\sigma^2}{\pi} \frac{2L_v}{\Omega^2} \left( \frac{1+12\left(\frac{\Omega}{L_v}\right)^2}{1+4\left(\Omega^2\Omega_v^2\right)^2} \right) \]

where:
- \( \sigma \) - is the dispersion of the turbulent movement;
- \( L \) - scale of turbulence;
- \( \Omega \) – spatial frequency;
- \( S \) - a distance between two points of the turbulence field.

In the modeling of turbulence, the Dryden and Karman models are most commonly used [9]. There, the variable component of wind speed is described by statistical methods. All of the models use, to a certain degree, assumptions about: homogeneity, isotropy and stationarity. Under these assumptions, the statistical characteristics depend only on the distance between the points and the averaging interval.

The wind distribution in space is considered to be frozen and, depending on the time, it is assumed that the airplane pierces this distribution (Taylor hypothesis). For isotropic turbulence estimation, two components of the random wind speed are used: component of the tangent to the trajectory \( V_t \) and the normal component \( V_n \).

The statistical processing of experimental results is reduced to approximation with empirical formulas, where spectral densities are fractionally rational functions of the frequency. [3, 9]. Thus, wind influences are represented as white noise that goes through linear forming filters with a classical structure. The spectral density functions are [9]:

In an urban environment quadrocopter flight, the presence of an air stream or a gust of wind may cause a strong turbulence to occur in unexpected locations. The reason for this is the interaction of air masses with different buildings [11].
The equations for the translational motion are obtained as a consequence of the theorem of varying the amount of motion.

\[ m \frac{d\mathbf{V}}{dt} = \sum \mathbf{F} \]

After substitution, the full differential equations for the movement of the center of mass of the quadrocopter are obtained:

\[ (5) \quad V_x = \frac{dV_x}{dt} = \frac{F_x}{m} = \omega_2 V_y + \omega_3 V_z; \]
\[ (6) \quad V_y = \frac{dV_y}{dt} = \frac{F_y}{m} = -\omega_1 V_x + \omega_3 V_z; \]
\[ (7) \quad V_z = \frac{dV_z}{dt} = \frac{F_z}{m} = -\omega_1 V_x - \omega_2 V_y. \]

The external forces acting on the axis of the coupled coordinate system of the quadrocopter are:

\[ (8) \quad F = \begin{pmatrix} F_x \\ F_y \\ F_z \end{pmatrix} = \begin{pmatrix} -G \sin(\theta) \\ (\omega^2 z + \omega^2 y + \omega^2 z) k - G \cos(\gamma) \cos(\theta) \\ G \cos(\gamma) \cos(\theta) \end{pmatrix}, \]

where \( f_i = k \omega_i^2 \) is the thrust generated by the \( i \)-th engine; \( G \cos(\gamma) \cos(\theta) \) is the force of gravity directed at the local vertical.

\[ \begin{array}{c}
\end{array} \]

Fig. 2 The forces and the moments in quadrocopter flight.

The description of the movement around the center of mass is carried out by integrating the derivative of the kinetic moment:

\[ (9) \quad \frac{d\mathbf{K}}{dt} = \sum \mathbf{M} \]

Complete equations for rotary motion around the center of the mass are:

\[ (10) \quad \dot{\omega}_x = \frac{1}{I_x} [M_x - (I_z - I_y) \omega_y \omega_z]; \]
\[ (11) \quad \dot{\omega}_y = \frac{1}{I_y} [M_y - (I_z - I_y) \omega_z \omega_x]; \]
\[ (12) \quad \dot{\omega}_z = \frac{1}{I_z} [M_z - (I_y - I_x) \omega_x \omega_y]. \]

The quadrocopter has a symmetrical structure with four propellers. Therefore, the cross inertia moments are very small and can be ignored.

The angular velocity of the rotor \( i \), designated \( \omega_i \), creates a force \( f_i \) in the direction of the axis of the rotor. The angular velocity and the acceleration of the rotor also create a reactive moment \( \tau_{M_i} \) around the axis of the rotor [7].

\[ (13) \quad \tau_{M_i} = b \omega_i^2 + I_M \ddot{\omega}_i, \]

where: \( b \) is a constant, proportional to the reactive moment,

\[ I_M \] is the inertia moment of the rotor.

Usually, the effect of the change in angular velocity is considered to be small, and is therefore omitted.

External moments acting on the axis of the body-fixed frame are:

\[ (14) \quad \mathbf{M} = \begin{pmatrix} M_x \\ M_y \\ M_z \end{pmatrix} = \begin{pmatrix} h k (-\omega_1^2 - \omega_2^2 + \omega_2^2 + \omega_3^2) \\ \tau_{M_1} - \tau_{M_2} + \tau_{M_3} - \tau_{M_4} \\ h k (\omega_1^2 - \omega_2^2 - \omega_2^2 + \omega_3^2) \end{pmatrix}, \]

where \( h \) is the distance between the rotor and the corresponding axis of the body-fixed frame.

The angular position of the quadrocopter relative to the ground coordinate system \( O_x, y, z \) is set by three angles: \( \psi \) - Yaw, \( \gamma \) - Pitch, \( \theta \) - Roll. The relationship between these angles and the angular velocities around the axes of the body-fixed frame are given by the following differential equations:

\[ (15) \quad \dot{\psi} = \frac{\omega_x \cos \gamma + \omega_y \sin \gamma}{\cos \theta}; \]
\[ (16) \quad \dot{\gamma} = \omega_x + tg \theta (\omega_y \cos \gamma + \omega_z \sin \gamma); \]
\[ (17) \quad \dot{\theta} = \omega_y \sin \gamma + \omega_z \cos \gamma. \]

The spatial displacement of the quadrocopter is described by means of the guiding matrix of directing cosines and the linear velocities in the body-fixed frame.

\[ (18) \quad \begin{pmatrix} \dot{x} \\ \dot{y} \\ \dot{z} \end{pmatrix} = C(\phi, \theta, \gamma) \begin{pmatrix} V_x \\ V_y \\ V_z \end{pmatrix}. \]

The system of equations (5 ÷ 8, 10 ÷ 18) is realized in the environment of Simulink. Four PID regulators are added to control flight height and angles \( \psi \), \( \theta \) and \( \gamma \). Atmospheric disturbances are presented with a Dryden model [14] and are added to the closed system (fig. 3).

Fig. 3 Quadrocopter flight model with added atmospheric disturbance.

4. Results

Fig. 4 shows the working of predetermined angles \( \psi \), \( \theta \) and \( \gamma \) from the quadrocopter without atmospheric disturbance.

Fig. 4 Angles of Yaw \( \psi \), Pitch \( \gamma \) and Roll \( \theta \) without added interference.

Figures 5 and 6 show the turbulent disturbances acting on the axes of the body-fixed frame. They are generated under the following conditions:

- Wind speed at the low-altitude – 8 (m/s);
- Probability of exceedance of high-altitude intensity: 10^{-2};
- Scale length at medium/high altitudes:533.4(m).
Fig. 5 Disturbances in the form of linear velocities on the axes of the body-fixed frame, in meter per second.

Fig. 6 Whirlwind disturbance on the axis of the body-fixed frame, in radians per second.

In fig. 7 is shown the influence of the disturbances on a quadcopter flight without change in the setting of PID controller shown in fig. 5 and fig. 6.

Fig. 7 Angles of Yaw $\psi$, Pitch $\gamma$ and Roll $\theta$ with added interference.

Fig. 8 Angles of Yaw $\psi$, Pitch $\gamma$ and Roll $\theta$ with added interference and increased robustness of regulators.

Changing the setting of PID controllers by increasing the robustness of the system reduces the impact of atmospheric disturbances but reduces the speed of the system. Figure 8 shows the change of the angles of Yaw $\psi$, Pitch $\gamma$ and Roll $\theta$ under the same initial conditions, with added disturbances and with the new settings of the PID regulators.

Fig. 9 Flight height variation at different wind intensities and increased system robustness.

Figure 9 shows the variation in flight height at different wind intensities and increased system robustness.

From Figures 7, 8 and 9 the following conclusions can be made:

- Angles Yaw $\psi$, Pitch $\gamma$ and Roll $\theta$, defining the spatial position and behavior of the quadrocopter, are influenced by the intensity of the wind, but with increasing system robustness, this influence weakens;

- The change in wind intensity has a greater effect on flight height than its angular position, and increased robustness can not compensate for atmospheric turbulence.

5. Conclusions

1. A mathematical model of a real quadrocopter is created;
2. The motion of a quadrocopter is modeled in the presence of atmospheric disturbances;
3. From the results obtained, it is possible to determine the upper limit of the atmospheric disturbances in which a quadrocopter can be used;
4. The quadrocopter whose model has been studied can be used in open spaces at winds up to 25 (m/s) and in urban environments at winds up to 10 (m/s).

ANALYSIS OF THE RELIABILITY OF DC BRUSHLESS ELECTRIC MOTORS WITH POWER UP TO 200W USED IN MAVs

M.Sc. Kambushev K.M. PhD.
Faculty of Aviation, Dolna Mitropolia – National Military University, Veliko Turnovo, Bulgaria
k_kambushev@mail.bg

Abstract: This report analyzes the reliability of DC brushless electric motors up to 200W. Reliability is calculated in accordance with the MIL-HDBK-217F Notice2 standard and NSWC-10 standard.

KEYWORDS: DC, BRUSHLESS, ELECTRIC MOTORS, RELIABILITY, 200W

1. Introduction

Today's micro air vehicle (MAV), with the development of technology and automatic control systems, are increasingly being used for both military and civilian purposes. Nowadays, MAVs are used for fun as well as important tasks such as:
- looking for injured in a distressed area;
- search and assessment in areas of disasters, accidents and environmental catastrophes;
- monitoring of forests, agricultural crops, agricultural activities;
- a flying platform for conducting experiments;
- different types of security, control and monitoring;
- mapping and geodetic measurements;
- performing various military operations.

Modern MAVs are a complex set of information sensors [3], automatic control systems [2], and powertrain assembled in the corresponding aerodynamic circuit. In order for the tasks to be performed, all elements of the MAV's must be highly reliable.

In MAVs are used brushless electric motors of up to 200W. This type of DC motors has the following advantages:
- wide range of speed adjustment;
- lack of nodes that require frequent maintenance (collector);
- can be used in explosive environments (no irritation);
- high overload capacity for a short time;
- high energy efficiency (over 90%)
- long life and high reliability due to the lack of brushes.

One of the main disadvantages is the higher price due to the more expensive materials.

2. Experimental part

Reliability of an electric motor means the property of the object to perform the assigned functions, preserving for a certain period of time the values of the established operating parameters within defined limits, corresponding to set modes and conditions of use, maintenance, repairs, storage and servicing.

The function of the reliability \( P (t) \), expressing the probability that the accidental processing of the motor to the failure \( \tau \) will be no less than the set work \((0, t)\), at the failure intensity \( \lambda (t) = \text{const} \) is calculated by [1]:

\[
P(t) = e^{-\lambda t}
\]

The probability of faultless operation of a small brushless electric motor up to 200W can be calculated using the following formula:

\[
P(t) = P_b(t)P_w(t)
\]

Where \( P_b \) is the probability of faultless operation of the bearings, and \( P_w \) is the probability of faultless operation of the coils.

Under normal operating conditions (temperature, revolutions, load and vibration), the bearing mounted in a small brushless motor must operate on average 77 000h or MTBF (number of hours that pass before a component, assembly, or system fails) = \( 77 000/(365\times24) = 8.8 \) years. The probability of failure is \( \lambda = 1/77 000 = 1.3\times10^{-5} \) 1/h. [4, 6]

The probability of faultless operation of the windings is determined by (1), \( \lambda = \lambda_w \). To find the failure rate, the average time of service expectation

\[
t' = T_w'\exp\left[-\alpha_t(\vartheta - \vartheta_{\text{max}})\right]
\]

which, in principle, depends on the time of service expectation of the winding. In eqn (3) \( \alpha_t \) is the temperature coefficient of time of service expectation, \( \vartheta \) is the temperature of the winding under operation and \( T_w' \) is the mean time of service expectation for the winding at the permissible temperature \( \vartheta_{\text{max}} \) for a given class of insulation and relative humidity from 40 to 60%. The higher the service temperature for the given class of insulation the longer the time \( T_w' \). Failures resulting from damaged soldered connections – due to breakage or aging - are also possible. Failure rate of winding including soldered connections is [4, 5]
Figures 1 and 2 show a rotor and stator of a 200W brushless DC motor.

The thickness of the conductor from which the winding is made is 0.25 mm. The maximum current for this engine is 16.7A. Probability of failure-free operation of the motor within the time period of 5000 h is \( P(t)=0.9467 \), i.e. if 100 such motors operate within the time period \( t = 5000 \) h, 6 motors out of these 100 will probably not survive.

The maximum current consumption of brushless electric motors up to 200W is in the range of 1.8A to 27A. Probability of failure-free operation of the motors within the time period of 5000 h is from \( P(t)=0.9214 \) to \( P(t)=0.95117 \).

3 Conclusions

From the calculations it can be deduced that the brushless DC motors placed in normal operating conditions have very high reliability. The bearings and windings used have a very long service life. If a suitable engine is selected when designing MAVs, its technical condition will mainly depend on the vibrations and mechanical loads that will affect it in flight.

With proper operation and timely prophylaxis, including regular bearing lubrication and dirt clearance, a high level of reliability can be maintained for a very long time.

EXPERIMENTAL AND NUMERICAL ANALYSIS OF WIND TURBINE MODEL

Biluš I., PhD. 1, Lešnik L., PhD. 1
University of Maribor, Faculty of Mechanical Engineering, Slovenia 1
ignacijo.bilus@um.si

Abstract: Global demand for electric energy is predicted to increase in the coming decades. Following this, different approaches for additional electricity production are analysed and tested worldwide. The EU supports the production and usage of electricity from renewable energy sources, particularly wind energy, because it provides electricity without giving rise to any carbon dioxide emissions. The presented work analyses the possibility for utilising of wind-generated electricity as a stand-alone system for small off grid cabin supply. The very basic turbine geometry was designed and numerically simulated with commercial CFD software. After that, the turbine model was printed using 3D printer and tested in laboratory environment. The comparison of numerically and experimentally obtained operating characteristics show reasonable agreement and strong potential for system optimisation and improvements.

Key words: wind turbine, CFD, experiment

1. Introduction

To obtain wind power, the kinetic energy of wind is used to create mechanical power which is converted into electricity with generator. This makes the wind as unlimited, free, renewable energy resource with high economic value and low maintenance cost. The wind turbines harmlessly generate electricity from wind passing by. Wind energy is far more ecofriendly than the burning of fossil fuels for electricity production. On the other side, the wind energy has disadvantages as well. The two major disadvantages of wind power include initial cost and technology immaturity.

Firstly, constructing turbines and wind facilities is extremely expensive. The second disadvantage is technology immaturity, which predominantly address the current technology limits for offshore machines to shallow-water sites at a cost premium. New technology is needed to lower costs, increase reliability and energy production, expand the resource area and mitigate known environmental impacts [1].

The land based wind turbine technology researches, on the other side, addresses performance and reliability issues that wind power plants experience throughout their life span and reduces system costs through innovative technology development. Present study, address the solution simplicity on the case of small off grid wind power system. It was assumed, that area that have adequate wind, is available. Therefore, the analysis started with search for a suitable turbine geometry solution.

2. Wind turbine geometry

To determine the optimal wind turbine geometry, it is necessary to select or define some parameters and quantities as speed, Reynolds number, profile type and its span wise angle/length distribution. The outer diameter limit was set to $d_{max}$<300 mm according to the inner diameter of test section.

According to the diagram shown at Fig. 1 we selected the SG6043 profile. The complete geometry of turbine blades was defined using Betz and Schmitz’s theory which provide the equations for the length of the blade profile and its angle distribution depending on the radius as follows [2].

Betz theory:

$$c_{Betz}(r) = 2\pi R \frac{1}{2g_{CL} A^2} \left(\frac{r}{R}\right)$$

$$\beta_{Betz} = \arctan\left(\frac{2}{3} R A_B\right) - \alpha_A$$

Schmitz theory:

$$c_{Schmitz}(r) = \frac{16 \pi r}{g_{CL} \sin\left(\frac{1}{3} \psi_1\right)}$$

$$\beta_{Schmitz} = \arctan\left(\frac{R}{\psi_1}\right) - \alpha_A$$

Fig. 1. $C_{p}/C_{d}$ ratio with angle of attack $\alpha_A$

The blade profiles were designed as shown at Fig.2.

The commercial CAD program was used for modeling of both turbine geometries. The Betz and Schmitz wind turbine runner models are shown at Fig. 3.
3. Numerical simulation

Operating characteristics of wind turbines were simulated using ANSYS-CFX. The simulation was set using Flow driven rigid body approach, where different prescribed mechanical torque values simulated the generator’s electric load.

The used governing equations were based on the conservation form of the Reynolds averaged Navier-Stokes (RANS) equations system. The first equation is continuity equation, which can be written as:

$$\frac{\partial}{\partial t} \rho + \frac{\partial}{\partial x_i} (\rho u_i) = 0$$

The second equation presents the equation for conservation of momentum:

$$\frac{\partial}{\partial t} (\rho u_i) + \frac{\partial}{\partial x_j} \rho u_i u_j = - \frac{\partial p}{\partial x_i} + \frac{\partial}{\partial x_j} \left( \mu + \mu_t \right) \frac{\partial u_i}{\partial x_j} - \frac{2}{3} \delta_{ij} \frac{\partial u_k}{\partial x_k}$$

where $p$ denotes the pressure, $u$ is the velocity, $\mu$ and $\mu_t$ are laminar and turbulent viscosity and $\delta_{ij}$ is the Kronecker delta function. Numerical modeling of turbulent flow is very complex process in which turbulence model play a significant role. It is used for calculation of fluctuating part of pressure and velocity in RANS equations. The appropriate turbulence model must be applied in order to accurately predict cavitation inception and detachment of the cavity from solid surface. In present study, the standard $k-\varepsilon$ model was used. It is a two-equation model which includes two extra transport equations which represent the turbulent properties of the flow.

$$\frac{\partial}{\partial t} (k) + \frac{\partial}{\partial x_i} (k u_i) = \frac{\partial}{\partial x_j} \left[ \left( \frac{\mu + \mu_t}{\sigma_k} \right) \frac{\partial k}{\partial x_j} \right] + P - \varepsilon$$

$$\frac{\partial}{\partial t} (\varepsilon) + \frac{\partial}{\partial x_i} (\varepsilon u_i) = \frac{\partial}{\partial x_j} \left[ \left( \frac{\mu + \mu_t}{\sigma_\varepsilon} \right) \frac{\partial \varepsilon}{\partial x_j} \right] + C_{1\varepsilon} \frac{\varepsilon}{k} P - C_{2\varepsilon} \frac{\varepsilon^2}{k}$$

The numerical domain was discretized by unstructured tetragonal mesh (Fig. 4). Grid dependence study was made using Richardson’s extrapolation where three meshes with different mesh densities were tested. The grid convergence index presenting the calculated uncertainty was less than 5% for fine mesh and less than 7% for medium mesh. In order to assure minimal discretization error, the finest mesh with total number of 1714660 elements was used for numerical analysis.

Defining the right boundary conditions, it is a key to a successful numerical simulation. The boundary conditions in pipe, where turbine runners were mounted were prescribed as shown at Fig. 5 and detailed in table 1.

3. Experimental setup

The wind turbine runners were mounted into the inlet pipe of radial fan test section in laboratory. The wind was produced using frequency regulated electric motor which power the fan, as shown at Fig. 6.

Wind turbine runners were directly connected to the axis of the generator. For the production of electrical energy, we used the permanent magnet brush DC motor, which operated in generator mode. The basic characteristics of motor are summarized in the table 2.

\[ U_i = U_M + I_R R_R \]

Where mechanical power depends on torque and constant \( k_m \) as follows

\[ P = M \omega = (k_m I_P) \omega \]

The wiring diagram of generator is shown at Fig. 7. The induced voltage on generator equals

\[ U_i = U_M + I_R R_R \]

Where mechanical power depends on torque and constant \( k_m \) as follows

\[ P = M \omega = (k_m I_P) \omega \]

4. Results

4.1. Numerical simulation results

We performed numerical simulations of the wind turbines using both geometries and two different wind speeds. The simulations we performed were transient. The angular velocity of rotor was zero at the simulation start. The simulations were stopped at the moment when rotor angular velocity become constant. In the continuation results will be presented for the case of wind velocity 16 m/s.

Fig. 8 shows operating characteristics for Betz geometry at 16 m/s wind speed. We used normalized values of power, which means that the power value is divided by the maximal power value. This allows us to present results in values between 0 and 1, where value 1 stands for best efficiency.

Fig. 9 shows velocity field and velocity vectors for Betz geometry at 16 m/s wind speed. CFD enables detailed analysis of flow variables and give us deeper insight of flow characteristics of machinery. Fig. 9 shows velocity field and velocity vectors for Betz turbine at 16 m/s. The point A represents a velocity field for lowest velocity ratio \( \lambda \). As we can see from the figure, the flow separation occurs in the point A. On the other hand, we have points B and C, which both have higher efficiency, and their velocity fields do not differ that much.

Fig. 10 shows operating characteristics for Schmitz geometry at 16 m/s wind speed. It is evident that characteristics show same trend comparing to Betz turbine characteristics shown at Fig. 8. The difference is at optimal value \( \lambda_{opt} \) which is \( \lambda_{opt,Schmitz}=3.3 \) and \( \lambda_{opt,Betz}=3.9 \). The reason for this is in different geometry of runners.

4.2. Experiment results

The measurement of operating characteristics was performed for both wind turbine runners. The “wind” velocity was increased using frequency regulated electric motor. The Fig. 12 show the turbine runner rotating frequency for different wind speeds and mechanical power measured with the DAQ system.

It is evident, that turbine rotating frequency achieved more than 6000 rpm or 100 Hz at the wind speed of 10 m/s. At this operating point, mechanical power of system equals \( P = 20 W \).

Since both turbine runners were 3D printed from PLA filament, wind velocity was not increased further due to the mechanical
properties (strength of material) limitation. According to this, operating measured characteristics did not achieve the peak as shown at Figs. 8 and 10, where velocity boundary condition was set to the value of 16 m/s.

5. Discussion and conclusions

The CFD results presented clearly show, that wind turbines have to be precisely designed for the area of operation. As we can see the performance of the wind turbine rotor begins to increase, up to the point where it reaches its peak at $\lambda_{opt}$. This peak represents the optimal operating point of the wind turbine. Past its peak, the performance begins to deteriorate.

Fig. 11. Velocity field for Schmitz turbine geometry at 16 m/s wind speed

The quantitative analysis of CFD results show that geometry according to the Schmitz theory performs a lot better. The difference was more evident at wind of 16 m/s, where the power output of the Schmitz geometry is 38.5W, while the Betz geometry only produces 14.8W. On the other hand, we have the 8 m/s wind where both geometries performed poorly, but still the Schmitz geometry output was 4.7W, while the Betz geometry produced only around 2.3W.

The reason for better characteristics of Schmitz runner geometry is in surface area of runner. If we look at Fig. 3 we see that the Schmitz geometry has a much larger surface area comparing to the Betz geometry, which helps to extract more energy from the wind.

Fig. 12. Measurement of operating characteristics for Schmitz turbine

The experimental analysis showed that used electric generator characteristics and analyzed runners are not compatible for the case of runners printed of PLA. To perform complete characteristics measurement, the generator should be optimized or runner’s material should be replaced with more rigid one.

In conclusion, we see that Schmitz geometry is more suitable, because it produces twice as much power.

SIMULATION OF THREE-DIMENSIONAL CAVITATION IN RADIAL DIVERGENT TEST SECTION USING DIFFERENT MASS TRANSFER MODELS

Lešnik L. PhD., Biliuš I. PhD.,
University of Maribor, Faculty of Mechanical Engineering, Slovenia

Abstract: Cavitation is a phenomenon of liquid transition to vapour which occur at sudden drop in pressure. It can be studied experimentally using visualization techniques or numerically using numerical packages. In order to numerically predict cavitation Reynolds Averaged Navier Stokes equations and an additional transport equation for the liquid volume fraction can be used. In the additional transport equation mass transfer rate due to cavitation is modelled using different mass transfer models. In the presented paper cloud cavitation in radial divergent test section was studied numerically using three different widespread mass transfer models. The models used were Zwart, Kunz and Singhal mass transfer models. Zwart model is a native model of ANSYS CFX program while other two were implemented to the program. Steady state and transient RANS simulations were performed using the simulation program, standard k-ε turbulence model and scalable wall functions. The results of numerical simulations were compared with the results of experimental measurements performed at the University of Grenoble. Based on the presented results we concluded that all mass transfer models correctly predict the area of cloud cavitation formation.

Keywords: Cavitation, mass transfer model, numerical simulations, radial divergent test section

1. Introduction

Cavitation is an unsteady, three dimensional, and periodic phenomenon of liquid transition to the vapor and back to liquid. It occurs at sudden drop in pressure. The positive effects of cavitation are commonly used in medicine while its negative effects impact on the operations of turbine and other machinery. The majority of developed models base on the homogenous fluid approach which treats the cavitation flow as a mixture of two fluids behaving as one fluid. They are often used because of its simplicity despite that they are not able to reproduce strong thermodynamic non equilibrium effects [2-5].

In order to evaluate the variable density field several different methods can be used. These methods usually imply a barotropic law, or a transport equations models for void ratio. The main difficulty in these equations is related to the formulation of the source term for vaporization and condensations process which can be modeled using different mass transfer models [8-10].

In the presented paper we tested the ability of three different mass transfer models to simulate 3D cavitation flow in radial divergent test section. The tested models were native CFX mass transfer model proposed by Zwart [8]. The model was compared with models proposed in work of Singhal et al. [9] and Kunz et al. [10]. All mass transfer models contain tunable parameters. The parameter values were determined using DOE in order to ensure congruent comparison or used models.

Obtained numerical results were compared with experimental results obtained at the University of Grenoble. From the obtained results we concluded that all mass transfer models correctly predict the area of cavitation cloud. This indicates that used mass transfer models can be used, with reasonable degree of confidence, for prediction of cavitation and cavitation erosion prediction in radial divergent test section.

2. Mathematical model

The governing continuity (1) and momentum equation (2) for a homogeneous mixture multiphase flow can be written as:

\[
\frac{\partial \rho}{\partial t} + \frac{\partial}{\partial x_i}(\rho v_i) = 0
\]

\[
\frac{\partial (\rho v_i)}{\partial t} + \frac{\partial}{\partial x_j}(\rho v_i v_j) = -\frac{\partial p}{\partial x_i} + \mu \left( \frac{\partial v_i}{\partial x_j} + \frac{\partial v_j}{\partial x_i} \right) + \rho f_{inter} = 0
\]

Where \( \rho \) is a mixture density, \( v \) is a time averaged mixture velocity, \( p \) represents pressure, \( \mu \) is a dynamic viscosity and \( f_{inter} \) volumetric forces. All phases are considered incompressible and they share the same velocity. The volume fraction equation for the liquid phase can be written as:

\[
\frac{\partial \gamma}{\partial t} + \nabla \cdot (\gamma \mathbf{v}) = \frac{m}{\rho_l}
\]

In the above equation \( m \) is the interphase mass transfer rate due to cavitation, \( \rho_l \) is liquid phase density and \( \gamma \) water volume fraction defined as:

\[
\gamma = \frac{\text{volumen kapljenje}}{\text{celomi volumen}}
\]

\[
\gamma + \alpha = 1
\]

2. Mass transfer models

Zwart cavitation model

The mass transfer model proposed by Zwart is based on a simplified Rayleigh-Plesset equation for bubble dynamics. The model is a native mass transfer model of CFX program. Specific mass transfer is formulated as:

\[
m = \begin{cases} 
-F_s \frac{3 \alpha r_{nuc} (1 - \alpha) \rho v}{r_b} \sqrt{\frac{2 p_v - p}{3 \rho_l}} & ; p < p_v \\
-F_s \frac{3 \alpha \rho v}{r_b} \sqrt{\frac{2 p_v - p}{3 \rho_l}} & ; p > p_v
\end{cases}
\]

where \( p_v \) presents vapor pressure, \( r_{nuc} \) is the nucleation site volumen fraction, \( r_b \) is teh radius of a nucleation site, \( F_s \) and \( F_c \) are empirical calibration coefficients for the evaporation and condensation processes. The default values of the above mentioned coefficients were used. They were set as follow: \( r_{nuc} = 5,0 \cdot 10^{-4} \), \( r_b = 1,0 \cdot 10^{-6} \), \( F_s = 50 \) and \( F_c = 0,01 \). \( \alpha \) present the vapour volume fraction.
Singhal cavitation model

The Singhal mass transfer model, known also as Full Cavitation Model, is also based on the reduced form of the Rayleigh-Plesset equation for bubble dynamics. Specific mass transfer model in simplified form can be formulated as follow:

\[
\dot{m} = \begin{cases} 
-C_e \frac{\sqrt{p_C}}{\rho} \rho_f \sqrt{\frac{2}{3} \left( p_f - p \right)} (1 - f_v); & p < p_f \\
-C_e \frac{\sqrt{p_C}}{\rho} \rho_f \sqrt{\frac{2}{3} \left( p_f - p \right)} f_v; & p > p_f 
\end{cases}
\]

In the above equation, \(f_v\) is the vapor mass fraction, \(k\) is the turbulence kinetic energy. \(S\) presents the surface tension. \(C_e\) and \(C_c\) are again empirical calibration coefficient with default values of \(C_e = 0.02\) and \(C_c = 0.01\), respectively.

In the above formulation we replace the vapor mass fraction by the vapor volume fraction \(\alpha\) as proposed by Huuva in [11].

Kunz cavitation model

The Kunz cavitation model is based on the work done by Markle et al. [12]. The mass transfer in this model is based on two different strategies for creation (\(\dot{m}^+\)) and destruction (\(\dot{m}^-\)) of liquid. The amount of liquid, which transforms to vapor, is proportional to the amount by which the pressure is below the vapor pressure. The creation of liquid is based on third order polynomial function of liquid volume fraction \(\gamma\). The specific mass transfer rate is formulated as:

\[
\dot{m}^+ = \frac{C_{prod} \rho_f Y^2 (1 - \gamma)}{t_m} \\
\dot{m}^- = \frac{C_{dest} \rho_f Y \min[0, p - p_v]}{(1/2 \rho_f v^2) t_m}
\]

where \(v\) is the free stream velocity, \(t_m = L/v\) is the mean flow time scale, where \(L\) presents the characteristics length scale. \(C_{prod}\) and \(C_{dest}\) are empirical coefficients with default values of \(C_{prod} = 100\) and \(C_{dest} = 100\).

3. Numerical model

In the presented study we considered water flow in radial divergent test section. The diameter of section test plates was 100 mm with 2.5 mm distance between plates. The inflow diameter was 16 mm with the radius of 1 mm at intake transition to test plate. Only 45° section of whole test section was modeled in the presented paper. The used geometry and mesh are presented in Fig. 1.

![Fig. 1. Used geometry of test section](image)

Grid convergence study was made using Richardson’s extrapolation where three meshes with different mesh densities were tested. The selected mesh for further work has 7.21 million elements with 5 layers of inflation at each wall. At the inlet and outlet, we applied with normal speed of 31.08 m/s and static pressure of 5.96 bars according to experimental study [13]. No-slip condition was applied on solid walls. Water and vapor volume fraction were set to 1 and 0, respective.

4. Experimental results

Experimental measurements are not part of the presented work. The results from experimental measurements are taken from work done at LEGI Institute University of Grenoble [13]. They are used only for validation of numerical results. Test section is schematically presented in Fig. 2. The study is not transl coś nie jest skomunikowane.

![Fig. 2. Schematic presentation of test section](image)

The cavitation cloud closing point obtained from experimental results is at radial distance of 22.5 mm from central axis of inlet. This is also the distance where maximal erosion of test plates was observed. The erosion, caused by cavitation, is concentrated in a ring of mean diameter similar to closing point of cavitation cloud and thickness of 8 mm.

5. Parameter determination

As can be seen in section 2 all mass transfer models employ some empirical parameters. The value of each parameter significantly influence evaporation and condensation mass transfer processes. The proper calibration of each parameter value is needed in order to achieve the accuracy of used mass transfer model.

Based on experience from previous study [14] several different optimization algorithms can be employed for determination of parameter values. In presented study we used Design of experiment (DOE) algorithm to explore influence of parameters values variation on obtained numerical results.

The results of cavitation patterns of flow in test section obtained using tuned and default values empirical parameters of Kunz are presented in Fig. 3.
The following Table shows default and calibrated values of empirical parameters for all three mass transfer models.

Table 1: Default and tuned values of empirical parameters.

6. Results

In order to perform transient simulations steady simulations were performed first. The results from steady simulations were further used as initial conditions for transient simulations. Fig. 4 presents the numerical results of maximal flow velocity in test section.

Numerical results of maximal flow velocity agree with experimental one where velocity of 65 m/s was obtained. Fig. 5 present numerical results of vapor volume fraction.

7. Conclusions

From the obtained results we concluded that all mass transfer models correctly predict the area of cavitation cloud. This indicates that used mass transfer models can be used, with reasonable degree of confidence, for prediction of cavitation and cavitation erosion prediction in radial divergent test section.

The presented results are showing that two distinct areas of high water velocity appear in radial divergent section. The first area appears at change of water flow direction (90° turn), while the second area appear behind cavitation cloud. The values of maximal flow velocity inside test section agree with experimentally obtained values. Behind the cavitation cloud the recirculation area is formed. The recirculation flow causes the shedding which is usually related to cavitation erosion. The area of cavitation cloud formation coincides with the low pressure area.

All cavitation-mass transfer models correctly predict the area of cavitation cloud formation. The front of cavitation cloud fluctuates in area where maximal erosion was obtained experimentally.

The values of empirical parameters for mass transfer models can be correctly determined using design of experiment algorithm.

ИССЛЕДОВАНИЕ РАБОЧЕГО ПРОЦЕССА БЕСКОВШОВОГО РОТОРНОГО ЗАГРУЗОЧНОГО ОРГАНА ПОГРУЗЧИКА

Нураков С.1, доктор технических наук, профессор; Мерзалинова Г.С.1, доктор технических наук, профессор; Тулеевская А.С.1, доктор PhD; Калиев А.Б.1, кандидат технических наук
1Евразийский национальный университет им.Л.Н.Гумилева (Казахстан)
adilbekk@mail.ru

1. Введение.

Сыпучие строительные материалы, транспортируемые погрузчиком, представляют собой разреженный грунт, щебень, песок и т.п., которые штабелируются на складах и используются в виде прим с гранями с углами отсыпки, которые различны для разных материалов и находятся в пределах от 20 до 45° [1].

В таком случае рабочий орган погрузчика внедряется в такую среду, сопротивление которой значительно меньше сопротивления при разработке этих материалов в целике. При этом основные энергозатраты загрузочного органа приходятся на процесс транспортирования захваченного материала и могут быть определены по широко известным зависимостям [2]. В связи с этим рассмотрим особенности процесса транспортирования сыпучего материала бесковшовым роторным загрузочным органом (БРЗО) новых конструкций погрузчиков сыпучих материалов [1, 3, 4, 5].

2. Основные результаты.

Для оценки транспортирующей способности БРЗО составим расчетную схему, из которой видно, как материал перемещается при вращательном движении загрузочного органа (рисунок 1). БРЗО выполняет функции транспортирования и разгрузки материала, взаимодействуя с сыпучим материалом, обладаемым свойствами трения и сцепления. Качество выполнения им транспортных функций и определяет его эффективность.

ИССЛЕДОВАНИЕ РАБОЧЕГО ПРОЦЕССА БЕСКОВШОВОГО РОТОРНОГО ЗАГРУЗОЧНОГО ОРГАНА ПОГРУЗЧИКА

Силовое поле, под воздействием которого находится кусок сыпучего материала при вращательном движении БРЗО, называется гравитационно-центробежным [6], т.к. любая частица, находящаяся в рабочем органе, испытывает одновременное активное воздействие силы тяжести и центробежной силы. Поэтому рабочий процесс и параметры рабочего органа, которые должны обеспечивать качественную загрузку и разгрузку, должны определяться с учетом условий движения материала с определенными свойствами по рабочим поверхностям в гравитационно-центробежном силовом поле. С позиции правильного учета всех факторов и расчета параметров загрузочного органа необходимо рассмотреть условия движения материала в плоскости вращения БРЗО.

Найболее глубоко проанализированы условия движения материала для роторов с горизонтальной осью вращения в работах [6, 7]. В этих исследованиях установлено, что в гравитационно-центробежном силовом поле движение частиц сыпучего материала, обладающего трением и сцеплением, происходит по поверхностям, описываемым уравнением логарифмической спирали:

\[ \rho = \rho_0 e^{-\mu \theta}, \]  

где \( \varphi \) - координата произвольной точки \( T \) на спирали \( AB \) в полярной системе
координат с осью \( PB \) и полюсом \( P \);
\( \rho_0 \) - радиус-вектор точки \( A \);
\( \mu = \tan \Delta \) - коэффициент, равный тангенсу угла \( \Delta \) между радиус-вектором точки \( T \) и полюсом \( P \);
\( h = g \omega_p^2 \),  

где \( g \) - ускорение свободного падения, м/с²;
\( \omega_p \) - угловая скорость вращения ротора, рад/с.

Для материалов, обладающих кроме свойства трения еще и сцеплением, уравнение спиральных поверхностей будет:

\[ \rho = \rho_0 e^{\mu \theta}, \]  

где \( \mu_s \) - коэффициент сопротивления внутреннему сдвигу, который при малых давленииях, как в ковше или роторе, определяется зависимостью:

\[ \mu_s = \tan \varphi_s = \tan \left( \frac{\pi}{4} + \arctg \frac{h}{2} \right), \]  

где \( \varphi_s \) - угол сопротивления внутреннему сдвигу [8].

В таком силовом поле, характеризующимся одинаковым силовым воздействием на частицы материала, изобары представляют собой концентрические цилиндрические поверхности с центральной осью, а силовые линии направлены радиально и лежат в плоскости вращения [2].

Для исследования процесса транспортирования грунта БРЗО положим в основу вышеприведенные теоретические положения и рассмотрим положение свободной поверхности
грунта в условном ковше на длине транспортирующих элементов по направлению вращения ротора (рисунок 2).

Решая совместно геометрические и математические задачи для ротора и свободной поверхности грунта в нем при транспортировании, определим транспортирующую способность БРЗО. Для этого на схеме (рисунок 2) показаны основные общепринятые геометрические параметры ротора и их обозначения.

Хотя роторное загрузочное устройство не имеет ковшей, а только по две транспортирующие пластины [3, 4, 5], введем понятие емкости условного ковша.

Рисунок 2 – Схема к определению полной выносной способности БРЗО

\( \varepsilon_{\text{онс}} \) – угол естественного откоса; \( \beta_0 \) – угол начала заполнения роторного загрузочного устройства транспортируемым материалом; \( \beta_p \) – угол разгрузки ротора; \( \beta_\varepsilon \) – угол, характеризующий длину приемного лотка (принимается в зависимости от конструкции угла)

Согласно рисунку 2, номинальная (полная, конструктивная) емкость ковша \( V_{\text{XII}} \) определяется из выражения:

\[
V_{\text{n}} = b_{p \cdot p} \frac{D^2 - d^2}{8} - \varepsilon.
\]  

(5)

Если свободная поверхность материала в ковше при данном значении угла \( \gamma \) занимает предельное положение, тогда получим максимальную полезную емкость условного ковша:

\[
V_{\text{m}} = V(\tau) = b_{p \cdot p} F_{\text{ABCD}}.
\]  

(6)

где \( F_{\text{ABCD}} \) – площадь сектора \( ABCD \), в который входит уравнение свободной поверхности \( AB \) (рисунок 1).

Следовательно, коэффициент транспортирующей способности условного ковша БРЗО можно записать в виде [9]:

\[
\kappa_{\text{вс}} = \frac{V_{\text{m}}}{V_{\text{n}}} = \frac{8F}{(D^2 - d^2) \varepsilon_0}.
\]  

(7)

при условии \( V_{\text{m}} = V_{\text{m,макс}} \)

где \( V_{\text{m,макс}} \) – максимальный объем условного ковша, \( m^3 \).

Так как бесковшовое роторное загрузочное устройство вращается с достаточно большой скоростью, и за время его движения транспортируемый материал не скатывается вдоль поверхности транспортирующих элементов, то можно считать, что условные ковши перекрывают друг друга без межковшового расстояния, т.е. поток материала, перемещаемого роторным устройством, является непрерывным. Исходя из этого, можно определить транспортирующую способность всего роторного загрузочного устройства. Для этого согласно схеме, изображенной на рисунке 2, необходимо определить площадь поперечного сечения роторного загрузочного устройства, занимаемую транспортируемым материалом от начала транспортирования, определяемого углом \( \beta_\varepsilon \) положения условного ковша, до момента выгрузки, определяемого углом разгрузки \( \beta_p \). Тогда объем материала в роторном устройстве будет определяться как:

\[
V_{\text{пм}} = F b_{p \cdot p} \frac{D^2 - d^2}{8} (\beta_\varepsilon - \beta_p).
\]  

(8)

где \( b_{p \cdot p} \) – средняя ширина роторного загрузочного устройства, м.

Угол разгрузки \( \beta_p \) можно определить аналитически из схемы (рисунок 2):

\[
\beta_p = \left( \frac{\pi}{2} - \beta_\varepsilon \right) + \frac{\pi}{2} + \beta_\varepsilon = \pi + \beta_\varepsilon - \beta_\varepsilon^*.
\]  

(9)

где \( \beta_\varepsilon^* \) – угол, характеризующий длину приемного лотка.

Значение угла начала захвата грунта транспортирующими элементами \( \beta_0 \) определяется нахождением точки пересечения угла естественного откоса \( \varepsilon_{\text{онс}} \) и радиуса роторного загрузочного устройства.

Если принять, что момент встречи транспортирующих элементов и откоса материала происходит на уровне оси вращения ротора, что является наиболее приемлемым условием заполнения ротора, то в выражении (9) учесть, что \( \beta_\varepsilon^* = \pi/2 \).

Тогда \( \beta_\varepsilon^* = \frac{\pi}{2} + \beta_\varepsilon^* \).

Отсюда полезная емкость БРЗО будет определяться из выражения:

\[
V_{\text{пм}} = F b_{p \cdot p} \frac{D^2 - d^2}{8} (\beta_\varepsilon - \beta_p) - b_{p \cdot p} S_{\text{абв}}.
\]  

где \( S_{\text{абв}} = \frac{D^2}{2} \psi + \varepsilon - \psi \left( D_\varepsilon^* - d_\varepsilon^* \right) \)

(10)

Номинальная емкость загрузочного устройства определяется как полный объем до сечения \( BB' \):

\[
V_{\text{пм}} = b_{p \cdot p} \frac{D^2 - d^2}{8} \left( \frac{\pi}{2} + \beta_\varepsilon^* - \beta_p \right) - b_{p \cdot p} \left( D_\varepsilon^* - d_\varepsilon^* \right) \}
\]  

(11)

Тогда коэффициент транспортирующей способности роторного загрузочного устройства будет определяться как:

\[
\kappa_{\text{вс}} = \frac{V_{\text{пм}}}{V_{\text{пм}}} = \frac{8nh_{\text{вн}}}{(D^2 - d^2) \varepsilon_0}.
\]  

(12)

3. Заключение.

Таким образом, с учетом особенностей конструкции бесковшового роторного загрузочного устройства и его заполнения сыпучим материалом выведено выражение для определения коэффициента транспортирующей способности БРЗО.

МЕТОДЫ ПОВЫШЕНИЯ НАДЕЖНОСТИ И ЭФФЕКТИВНОСТИ СИСТЕМЫ УПРАВЛЕНИЯ ЭКСПЛУАТАЦИЯ АВТОМОБИЛЕЙ

d.т.н. проф. Шатманов О.Т., д.т.н., проф Жанбиров Ж.Г., старший преподаватель Асаналиев Т.М., аспирант Кожогулов М.А.

Кыргызский государственный университет строительства, транспорта и архитектуры имени Н. Исанова г. Бишкек. Кыргызстан

Предложен метод поиска оптимальной системы управления эксплуатация автомобилей. Внедрение результатов исследования по совершенствованию надежности системы управления эксплуатации автомобильного парка позволило получить по предварительным расчетам экономический эффект более 10 млн тенге, рентабельность предприятия составила 32.69% против 22.55 в 2017 году и повышение производительности на 12%.

Ключевые слова: автотранспорт, факторы, анализ, социально-экономика, повышение, надежность, эффективность, учет, финансы.

METHODS TO IMPROVE THE RELIABILITY AND EFFICIENCY OF THE CONTROL SYSTEM OPERATION OF VEHICLES

Ph. D. Prof. Shatmanov O. T., Ph. D. prof Ganbarov J. G., senior teacher T. M. Asanaliev, PhD student Kojobogulov M. A.

Kazakh Academy of transport and communications named after M. Tynyshpaeva Almaty. Kazakhstan

The method of search of optimal control system operation of cars is offered. The implementation of the results of the study to improve the reliability of the fleet operation management system allowed to obtain according to preliminary calculations the economic effect of more than 10 million tenge, the profitability of the enterprise amounted to 32.69% against 22.55 in 2017 and an increase in productivity by 12%.

Key words: motor transport, factors, analysis, social economy, increase, reliability, efficiency, accounting, Finance.

Введение. Повышение эффективности эксплуатации автотранспорта, в связи с изменениями на рыночном пространстве требует совершенствования методов управления автотранспортных предприятий. Рынок определяется тремя особенностями, указанных ниже [1]:

- формирование объема обслуживания для потребителей;
- определение размера прибыли с любого вида эксплуатации автотранспорта;
- наличие стратегии развития предприятия.

Для достижения цели эффективного выполнения стратегического плана нужно планировать текущие действия. Как перечислено выше, автотранспортное предприятие для реализации своего стратегического плана должно иметь планы пошаговых действий [2].

Совершенствования устойчивости управления цепи эксплуатации автотранспорта является надежность обслуживающих автомобилей, профессиональная подготовка водителей и техническое состояние автомобилей, «своевременное» и качественное выполнение заказов.

Эффективность финансовой устойчивости автотранспортных предприятий зависит от правильного использования автомобилей в их списке. Поэтому организационные работы следует начинать с производительности работы автомобилей $W_a$, а для этого можно применить следующее уравнение [3]:

$$W_{ab} = g \gamma / t_{оборот}$$  \hspace{1cm} (1)

где $g$ – грузоподъемность автомобилей;
$\gamma$ – кратности использования грузоподъемности автомобилей;
$t_{оборот}$ – время для выполнения одного заказа автомобилем или оборотний период.

Если для случая выполнения заказа используются несколько или разные грузоподъемные автомобили, то количество необходимых автомобилей определяется следующим образом:

$$N_{ab} = W_{ж}/W_{ab}$$  \hspace{1cm} (2)

А график передвижений автомобилей во время выполнения заказа планируется в связи с производительностью механизмов в местах загрузки и разгрузки.

Особенности методики планирования эксплуатации автотранспорта. Точное время выполнения заказа $t$, то есть время эксплуатации автотранспорта должно соответствовать этим условиям $t_b \leq t \leq t_o$, началу и окончанию работы в местах принятия грузов. По этой причине, при планировании эксплуатации автотранспорта, нужно определить подготовку специального места разгрузки грузов в местах принятия, для этого выполняются процедура расчета по нижеуказанным условиям [5,6]:

$$T_D \leq t + T_{ap}$$  \hspace{1cm} (3)

где $T_D$ – готовое время принятия груза, привезенного автомобилем;
$T_{ap}$ – периоды времени автомобилей с грузом.
Если во время приезда автомобиля с грузом его место для разгрузки не готово, то он может простоять, такое время простоя \( t \) – обозначают, и их можно распланировать в качестве пошаговой таблицы передвижений. Если такое условие соблюдается и сохраняется, то план использования автомобилей можно назвать оконченным а \( t > t_c \). Если для оказания транспортных услуг или выполнения работ используются несколько автомобилей, то подготовка механизмов к разгрузке товаров и их свободное состояние влияет на эффективность эксплуатаций автотранспорта, поэтому осуществляется рабочая таблица или график работы автомобилей в зависимости от производительности труда разгрузочных механизмов [7,8].

Для этого должны выполняться требования, указанные ниже:

\[
T_{КДД} \leq t - T_{авзж} - \sigma \cdot g_{\text{min}} / W_{TK} - T_{КЖ}
\]

где \( t_{тэд} \) – готовое время для загрузки грузов загрузочных устройств;

\( T_{авзж} \) – время начиная с загрузки грузов автомобиля и до места назначения;

\( g_{\text{min}} \) – самая низкая грузоподъемность участников в работах эксплуатации автомобилей;

\( W_{тк} \) – производительность труда загрузочных устройств;

\( T_{КЖ} \) – время, расходуемое на дополнительные работы при загрузке груза.

После определения графика передвижения, в период \( t \)-времени в зависимости от марки автомобиля готовятся места для разгрузки и загрузки. Для этого с помощью этого уравнения готовятся площадки и места загрузки разгрузки или выбирается вид и марка автомобиля в соответствии с шириной площадки [9]:

\[
t_{i_г} \leq t - 2T_{авзж} - 6g_{\text{ет}} / W_{КЖ} - T_{д}^* \quad T_{КЖ} \leq t - T_{авзж} - t_{i_1}
\]

где \( t_{i_1} \) – период последней разгрузки груза;

\( T_{д} \) – время планируемого передвижения автомобиля или эксплуатации автотранспорта;

\( T_{авзж} \) – время загрузки автомобиля начиная от постоянного места до места загрузки груза;

\( t_{i_г} \) – время начала работы автомобиля.

Поэтому руководители и специалисты автотранспортного предприятия в соответствии с видом заказа, расположения и подготовкой грузов, готовят конкретные автомобили для обеспечения эффективного выполнения заказа, принимают решение о том, чтобы взять от их передвижения как можно больше пользы и прибыли.

\[
T_{КДД} \leq t - T_{авзж} - \sigma \cdot g_{\text{min}} / W_{TK} - T_{КЖ}
\]

Целью работы - исследование основных требований, предъявляемых к таким системам являлась их высокая управляемость в изменяющихся внешних условиях функционирования при гарантированном достижении заданного результата для автотранспортных предприятий.

Исследование решений системы. К надежности системы управления эксплуатацией автотранспорта влияют стоимость и изменение тарифа на рынке транспортных услуг.

В основном установление тарифа в зависимости от пройденного пути рассчитывается от марки автомобилей и дальних дорог, от видов грузов и грузоподъемности.

Установление тарифа в зависимости от пройденного пути происходит путем двустороннего заключения договора, после того, как заказчик определил, какого вида автомобиль, для чего он необходим. Тариф, устанавливаемый по времени, назначается на 1 час, 2 часа или на 1 рабочий день. Себестоимость эксплуатации автотранспорта определяется по формуле:

\[
C_m = \left( C_{ос} g + C_{пост} \frac{L_{д}}{V_{с}} + t_{мм} \right) / g_s
\]

где \( C_{ос} \) – сумма оборотных средств загружаемая на 1 км пробега автомобиля, тенге;

\( L \) - расстояние, км;

\( g \) – коэффициент использования пробега;

\( C_{пост} \) – сумма постоянных средств загружаемая на 1 км пробега автомобиля, тенге;

\( V_{с} \) – техническая скорость автомобиля, км/ч.;

\( t_{л} \) – время простоя под погрузки и разгрузки автомобиля, ч.;

\( G \) - грузоподъемность, т;

\( S \) - коэффициент использования грузоподъемности автомобиля.

Рентабельность эксплуатации автотранспорта в расчете на 1 тонну груза определяется по формуле:

\[
r_m = \frac{d_m - C_{мм} * 100}{7}
\]

где \( d_m \) – тариф эксплуатации автотранспорта на 1 тонну груза.

Предварительно запланированный тариф эксплуатации автотранспорта или рентабельности рассчитывается таким образом:

\[
d_m = \frac{C_m (r_m + 100)}{100}
\]

Как дано в уравнениях выше, объемы прибыли, упущенной во время простоя автомобилей в процессе эксплуатации автотранспорта восстанавливаются за счет заказчика. Такое обстоятельство должно заранее полностью оговорено заказчиком, а также обсудить заранее стоимость услуг. Учитывая такие возможные неожиданные случаи простоя, стоимость оказание транспортных услуг определяется по формуле:

\[
B = C_{mb} + T \cdot C_{min} + P \cdot C_{мм}
\]

где \( C_{mb} \) – тариф заказа, тг;

\( T \) – время автомобиля, проведенное у заказчика, час.;

\( C_{min} \) – тариф свободного простого автомобиля на 1 час во время загрузочно-разгрузочных работ тг/час.;

\( P \) – выполненный объем работ, ткм;

\( C_{мм} \) – тариф использования автомобиля за 1-тт/ткм.

Тарифы являются задачей не только хозяйственного производства и внутреннего планирования автотранспортного предприятия.

Сокращает тариф или уменьшает стоимость транспортных услуг за счет уменьшения расстояний между постоянным местом расположений или временной стоянкой автомобилей и мест загрузки.
грузов, однако, объем выделяемых средств на организацию временной стоянки и материально-технической базы должен обеспечить получение запланированную сумму прибыли.

Поэтому для организации временной стоянки с материально-технической базы автотранспортным предприятиям необходимы многие специальные процедуры организации, показанных ниже на рисунке1.

Рис. 1- Схема организации материально-технической базы временной автомобильной стоянки эксплуатации автотранспортных предприятий

Как показано на рисунке 1, для эффективного использования любых автомобилей нужна специальная временная стоянка, средства и устройства для их технического ремонта и профилактических работ, места для хранения запасных частей, места для питания и отдыха водителей и работников. А также, путем заключения точно определенного двустороннего договора между заказчиком и эксплуатацией автотранспортом, также рассматриваются дополнительные действия и процедуры, выгодные обеим сторонам.

Общеизвестно, что все технологии и техники требуют технического ремонта и профилактики, замена запасных частей и инструментов автомобилей в необходимый период. Поэтому для обеспечения непрерывного повышения технической подготовки автомобилей, необходимо чтобы поблизости была специальная материально-техническая база. То есть для обеспечения финансовой эффективности автотранспортного предприятия, нужно уметь сохранить условия его внутренних динамических механизмов.

Внизу на рисунке 2 представлены принципиальная схема организации и управления грузовыми автомобилями на объекте.

где АП – автотранспортное предприятие; ПС – производители сырья; ТТ – производители готовой продукции; Д – готовая продукция; ШД – месторасположение производителя необходимых полуфабрикатов и сырья.

Рис. 2- Принципиальная схема организации на объекте

График строительства конкретного объекта рассчитан таким образом, что строителям необходимо своевременно в нужном объеме и количестве доставить готовые строительные материалы. На объекте отсутствует место или склады для хранения строительных материалов. На обслуживание строительного объекта привлечены 38 грузовых автомобилей, в частности 20-самосвалов марки КАМАЗ, 8-бортовых КАМАЗов, 5-автомобилей марки ГАЗЕЛЬ, 3 самосвала марки Газ-53 и 2-автокрана на базе Зил.

Однако, для организации временных стоянок и пунктов требуется дополнительные затраты, сумма которого определяется по формуле:

$$ P_1 = \sum_{i=1}^{k} m_1 L_{ij} = A_1 $$

(10)

и интенсивность выполнения эксплуатации автотранспортных процессов определяется по следующей формуле:

$$ I_1 = \sum_{i=1}^{k} m_1 L_{ij} / t_1 = A_1 / t_1 $$

(11)

gде $k$-показатель необходимых материально-технических ценностей для организации временных стоянок и пунктов; $m$ - эксплуатации автотранспорта возможность автотранспортного предприятия.
где \((Ai) – строительная компания (Bi) - автотранспортное предприятие (Ci) – склад строительных материалов и Li – расстояние между объектами.

Рис.3- Предложенная схема организации эксплуатации грузовых автомобилей

Таблица 1- Расчетная стоимость организаций временных автостоянок

Общая месячная сумма затраты необходимых для организаций и содержания временных автостоянок составляет 11 050,0 долл. США.

Для сравнения рассмотрим затраты грузовых автомобилей обслуживающих объектов заказчика в зависимости от расстояния расположения автотранспортных предприятий. Расход топлива -40 л/100 км, стоимость топлива 110 тг/л, другие затраты принимаем в расчете 20% от стоимости топлива, таким образом приведенная стоимость топлива равна 132 тг/л или 6,0 долл. США.

Если учесть, что расчет произведен на один конец, общая стоимость умножается на два, тогда график затраты холостого пробега автомобилей от автотранспортного предприятия до объекта заказчика выглядит таким образом.

Как видно их графика, если расстояние превышает более 40 км руководству автотранспортного предприятия экономически рационально организовать специальные пункты ТО и ТП автомобилей, пункт для отдыха и питания водителей и ремонтников, а также других лиц привлеченных на выполнение конкретного задания. Организован в месте где расположено главное автотранспортное предприятие и поблизости от главной строительной площадки на расстоянии Lj временная стоянка материально-технической базы. Участвующие в работах эксплуатации автотранспортники все автомобили, водители и технические работники располагаются в этой стоянке и для них организовываются все жилищно-социальные условия. Если место нужное для строительства назвать (К), а место эксплуатации автотранспорта стройтных материалов (Д), то их расстояние не должно увеличивать объем свободного простора автомобилей.

Результаты внедрение предложенной системы управления автотранспортными эксплуатацией грузовых автомобилей.

Нижеприведены экономические показатели ТОО «Бастау» за отчетный год доход от услуг эксплуатации автотранспортов уменьшился на 13 658, 0 тысяч тенге, то есть на 35, 3 %, а себестоимость оказанных услуг, напротив, возросла на 10 305, 5 тысяч тенге. Причину этого роста можно объяснить ростом материальных расходов на 7684, 0 тысяч тенге. И если общий доход в 2017 году составил 7601,0 тысячи тенге, то в 2015 году предприятие получило убыток в 16 363,0 тысяч тенге. Причину тому - в увеличении периодических расходов на 2585,3 тысячи тенге, в результате чего убыток от основной работы составил 21 674, 3 тысячи тенге, а доход от неосновной работы в 2017 году составил 16380,8 тысяч тенге. Общий доход по результатам 2010 года показал убыток в 4 875,0 тысячи тенге, а в 2017 году 5 293, 5 тысяч тенге.

Среднее количество сотрудников по списку уменьшилось на 4 человека, а зарплатный фонд уменьшился на 56,8 тысяча тенге, однако среднегодовая зарплата сотрудников, напротив, возросла на 1,9 тысяч тенге, что объясняется
Среднегодовая стоимость основных фондов возросла на 10,626,0 тысяч тенге, то есть на 62 процента, однако фонд отдачи уменьшился на 1,25 тг, то есть на 60 процентов.

Причина снижения связана с уменьшением объема оказанных услуг. В связи с этим проанализируем влияние основных средств на объем оказания услуг автомобилейм эксплуатации автотранспорта.

Объем прибыли в результате использования предлагаемой системы управления превысил 10 000 000 тенге, рентабельность предприятия в сравнении с 2015 годом, согласно отчету по итогам 2017 года, возросла с 22,55 до 32,69, производительность труда возросла на 12 процентов.

Выводы. В соответствии с общей теорией систем, локальная транспортная система может быть определена, как расширенно - интегрированная транзитная система. Произведенные исследования позволяют сделать следующие основные выводы:

- Создание научных основ развития системы организации и управления автотранспортного предприятия и новые технологии дают экономике Казахстана новый уровень качества автотранспортных услуг, что приведет к снижению уровня транспортных расходов в ВВП республики на 20-25%.
- Внедрение результатов исследования по совершенствованию надежности системы управления эксплуатации автомобильного парка позволили получить по предварительным расчетам экономический эффект более 10 млн тенге, рентабельность предприятия составила 32,69% против 22,55 в 2017 году и повышение производительности на 12%.

Аннотация: В работе предлагается метод планирования маршрута движения БТС с учетом неголономности связи гусеничного движителя с опорным основанием. Для этого уточняется математическая модель движения гусеничной машины, предлагается метод определения коэффициента сопротивления боковому уводу в режиме реального времени, разрабатывается алгоритм планирования маршрута движения на основе диаграммы Вороного. Предложенные решения позволяют синтезировать корректующую матрицу управления, обеспечивающую повышение устойчивости движения

Ключевые слова: Гусеничное транспортное средство, диаграмма Вороного, траектория движения, математическая модель.

Abstract: The paper proposes a method for planning the route of movement of an unmanned vehicle (UTV), taking into account the nonholonomic nature of the link between a tracked propulsion unit and a support base. To do this, a mathematical model of the tracked vehicle movement is specified, a method is proposed for determining the lateral drag coefficient in real time, and an algorithm is developed for planning the route of movement based on the Voronoi diagram. The proposed solutions allow to synthesize a corrective control matrix that provides improved motion stability.

Keywords: tracked transport vehicle, Voronoi graph, motion trajectory, mathematical model

Введение

Решение транспортных задач в условиях отсутствия информации в том наиболее эффективно с использованием быстродействующих гусеничных машин. Большая привлекательность маршрутов, тяжелые погодные условия ставят вопрос о целесообразности применения автономных беспилотных систем управления. Задача создания автономной системы управления гусеничной машиной осложняется недостаточной информативностью существующей математической модели движения. Неголономность связей движителя с опорным основанием, параметры и физико-механические свойства которого носят случайный характер и не позволяют достичь высокого качества процесса управления гусеничной машиной. Таким образом, требования к алгоритму беспилотного транспортного средства должны включать в себя построение маршрута по предварительно заданным данным и корректировка его в соответствии с окружающей обстановкой. Траектория движения должна учитывать текущие параметры взаимодействия как внутренней механической системы, так и взаимодействия ее с опорной поверхностью. Также необходимо предусмотреть обеспечение гарантированного зазора при обходе препятствий для обеспечения безопасного движения.

Целью работы является создание автономной беспилотной системы управления и для ее достижения необходимо решение нескольких базовых задач. Первая – создание алгоритма построения маршрута. Вторая – уточнение математической модели движения гусеничной машины. Третья – получение данных о параметрах взаимодействия гусеничного движителя с опорной поверхностью. В данной работе проводится анализ существующих методов планирования маршрутов, выявляются соответствующие проблемы и предлагаются пути их решения.

1 Анализ существующих методов планирования маршрута

Для построения маршрута применяются различные методы. Анализ опубликованных работ по этому направлению позволяет выделить два подхода: вычисление траектории в заранее известном статическом окружении и огибание обнаруженных препятствий с учетом поступающей от датчиков информации. Наибольший результат наблюдается при совместном использовании этих подходов [1].

Расчет траектории в статическом окружении позволяет спланировать маршрут, отвечающий заданным параметрам, например, кратчайший путь, определенная кривизна, наименьшее затраченное время и т.д. Задача нахождения пути между начальной и конечной точками решается различными путями. Наиболее часто упоминаются такие методы, как метод потенциальных полей, метод дорогой карты, генетический метод, применение нейронной сети и другие [1].

Методы, основанные на том или ином виде «машины обучения» (генетический метод, нейронная сеть), заключаются в многократном проигрывании заданной ситуации со случайным изменением параметров либо поведения объекта. Вариант, дающий наилучшие результаты, становится базовым для дальнейших мутаций. Высокий потенциал приспособляемости является несомненным достоинством методов. Однако высокая трудоемкость реализации и требования к мощности вычислительных ресурсов затрудняет их практическое применение.

Методы дорогой карты используют построенный на известной карте вокруг препятствий каким-либо образом граф (Roadmap). При этом предлагается множество способов построения дорогой карты: граф видимости [3], клеточное разбиение [4], быстрорастущие случайные деревья (RRT) [4, 6] и многие другие.

Ниже приводится пример реализации построения маршрута на основе диаграммы (графа) Вороного [7, 8]. Данный граф обладает очень важной для навигации особенностью – он проходит на наибольшем расстоянии от ближайших граней. Из приведенных данных следует, что маршрут, построенный на основе графа Вороного, является наиболее безопасным с точки зрения столкновения с препятствиями.

Движение безкипажного транспортного средства в естественном динамическом и/или неизвестном окружении сопровождается появлением не учтенных препятствий на заранее вычисленном маршруте. Для обеспечения безаварийного движения необходимо вносить корректировки. Во многих случаях для этого применяются алгоритмы семейства Bug [1, 9]. Кроме того, существуют модификации различных методов, например, потенциального поля, графа Вороного и т. п. [10, 11].

2 Формирование облика алгоритма планирования маршрута

В качестве основы для маршрута будет использован граф Вороного, преимущества данного метода описаны выше. На рис. 1 представлено построение маршрута. Вначале (рис. 1, а)
осуществляется построение графа, вокруг препятствий. Начальные и конечные точки отмечены символами «о» и «+» соответственно. В дальнейшем происходит вычисление кратчайшего маршрута, основанного на линиях графа. Полученная траектория показана на рис. 1 б) и выделена серым цветом.

При проектировании маршрута необходимо математическая модель движения машины. Известные модели требуют корректировки, учитывающие дополнительные ограничения, определяемые алгоритмом функционирования системы автономного управления. В связи с этим, в данной работе используется модель, новизна которой состоит в том, что учитываются упруго-инерционные свойства системы управления поворотом (упруго-инерционные свойства системы «двигатель-трансмиссия-движитель»). Это позволяет более точно моделировать качество переходных процессов. Кроме того, в математической модели принято, что момент сопротивления формируется силами бокового увода элементов двигателя. При этом функция коэффициента сопротивления уводу от угла скольжения является нелинейной. Математическая модель представлена в виде системы дифференциальных уравнений (1).

Первые два уравнения системы описывают поступательное движение машины в продольном (x) и боковом (y) направлениях. Третье уравнение определяет вращательное движение машины относительно вертикальной оси (z) с учетом действия центробежной силы. Четвертое уравнение определяет криволинейный процесс в приводе управления в системе «двигатель-трансмиссия-машина».

В этом координатах плоскопараллельное движение машины определяется следующей системой дифференциальных уравнений:

\[ \begin{align*}
V_x &= b_y(f_d - s) - V_x(t) \\
\dot{m}V_x &= nV_x + \sum C \dot{\theta}_i \\
\dot{\theta}_i &= -mV_x \theta_i - \sum C \dot{\theta}_i \chi - l \theta_i - C_m \theta_i - b_d \theta_i + m(t)
\end{align*} \]

где: \( m \) – масса машины; \( V_x, V_y, \dot{V}_x, \dot{V}_y \) – продольная и поперечная скорость и ускорение соответственно; \( \omega_z \), \( \dot{\omega}_z \) – угловая скорость и ускорение двигателя соответственно, приведённая к оси Z; \( g \) – ускорение свободного падения; \( f_d \) – динамический фактор; \( C_m \) – коэффициент сопротивления движению; \( \theta_i \) – угол и угловая скорость двигателя; \( l \) – расстояние от оси задней пары опорных катков до центра масса; \( b_d \) – момент инерции машины; \( J_d \) – момент инерции двигателя, приведенный к оси Z; \( b_d \) – угол и угловая скорость двигателя приведенная к оси Z; \( b_{dis} \) – коэффициент сопротивления тяги; \( C_{tor} \) – приведенная жесткость системы управления.

Рис. 1 – Построение графа Вороного на области 20x20 с препятствиями (а) и нахождение кратчайшего маршрута от начальной точки «о» к конечной точке «+» (б).

Стоит учесть, что перемещение реального транспортного средства в отличие от материальной точки осуществляется с ограничениями, обусловленными условиями взаимодействия как внутри механической системы, так и с опорной поверхностью. Поэтому данная траектория не обеспечивает оптимального энергоэффективного движения и наименьшего времени пути.

Следующий этап построения маршрута заключается в анализе траектории с точки зрения математической модели движения гусеничного транспортного средства. Кратчайшая траектория не всегда может обеспечить движение с оптимальной скоростью, а, следовательно, наименьшее время прохождения пути. Ограничение минимального радиуса поворота в зависимости от текущей скорости движения в определенных условиях может привести к столкновению с ограждающими препятствиями. Для обеспечения безопасного движения требуется снизить скорость. Скорость движения реальной машины может так же ограничиваться следующими факторами: обеспечение проходимости машины, планировки входа в движение по неровностям, энергоэффективности при вариации коэффициентов сопротивления движению и повороту, а также обеспечение тягово-сцепных свойств (ограничение буксования двигателя). Отсутствие коэффициента сцепления (сопротивления тяги). Из приведенного следует, что маршрут должен корректироваться в зависимости от значения физико-механических свойств опорного основания, параметров взаимодействия с движителем, измеряемых в режиме реального времени.

В дальнейшем происходит вычисление кратчайшего маршрута, основанного на линиях графа. Полученная траектория показана на рис. 1 б) и выделена серым цветом.
ры, в свою очередь, является функцией угла скольжения элементов движителя [12]. Измерение коэффициента сопротивления боковому уводу определяется по величине боковой силы, действующей на балансир опорного катка. При этом определение углов скольжения элементов движителя является наиболее сложной и не до конца решенной задачей. Одним из наиболее известных методов определения углов скольжения является в использовании оптических датчиков [13, 14], при котором выполняется анализ движения характерных точек опорной поверхности, выделенных на цифровом изображении. Упомянутый способ уже нашел свое применение в автомобильной промышленности, ведутся работы по расширению возможностей применения при низких скоростях движения на неровной поверхности, т.е. для внедорожной техники [15, 16]. Другой подход состоит в использовании координат GPS [17, 18]. Это позволяет исключить влияние внешних факторов, таких как запыленность, грязь, осадки, иней и туман. Так, при изучении особенностей поведения гусеничной машины на различных типах грунта реализован способ определения углов скольжения элементов конструкции движителя по отношению поперечных и продольных скоростей [19].

В ходе испытаний определялись координаты двух разнесенных приемников GPS. Анализ полученных данных позволил найти реальный угол скольжения в каждый отдельный момент времени. В дальнейшем была найдена зависимость коэффициентов сопротивления боковому уводу от углов скольжения элементов конструкции гусеничного движителя. На рис. 2 а) приведены результаты экспериментального определения коэффициента сопротивления боковому уводу от углов для двух типов грунтов для гусеничной машины: 1 – денистый грунт; 2 – песчаный грунт. На рис. 2 б) приведены аппроксимированные зависимости для различных грунтов при вариации коэффициента сопротивления повороту от 0,1 до 0,8.

Приведенные зависимости позволяют предложить достоверный способ определения типа грунта, по которому движется машина. Таким образом, становится возможным корректировать управляющие воздействия и собственные параметры транспортной машины в соответствии с текущими измеренными физико-механическими свойствами опорной поверхности.

3. Выводы.
1) На основе анализа известных методов планирования маршрута движения автономной транспортной машины в области с препятствиями установлено, что одним из эффективных алгоритмов является построение траектории на основе диаграммы Воронова.
2) Установлено, что траектория движения должна учитывать текущие параметры взаимодействия как внутри механической системы, так и взаимодействия ее с опорной поверхностью. Также необходимо предусмотреть обеспечение гарантированного зазора при обходе препятствий для обеспечения безопасного движения.
3) Проектируемый маршрут движения необходимо уточнять в соответствии с уточненной математической моделью объекта управления, отличающейся от известных тем, что учитываются упротно-инерционные свойства системы управления, момент сопротивления формируется силами бокового увода элементов двигателя. Эта функция является нелинейной, что определяется неголономностью связи движителя с опорным основанием.
4) Уточнение проектируемой траектории должно обеспечить движение без бокового заноса, проходимость машины, плавность хода при движении по неровностям, энергоэффективность при вариации коэффициентов сопротивления движению и повороту.
5) Разработан метод расчетно-экспериментального определения коэффициента сопротивления боковому уводу элементов конструкции движителя, как функции угла скольжения.

ИЗПИТВАНЕ НА АВТОМАТИЗИРАНА СИСТЕМА ЗА КОМПЛЕКСЕН НЕРАЗРУШАВАЩ КОНТРОЛ НА МЕТАЛНИ МАТЕРИАЛИ

Джуакев Б.1 д-р Ангелов В.2, д-р Златков М.2, Костадинов П.3
ТУ-София 1, Институт по механика - БАН2, ВТУ „Тодор Каблешков“3

Резюме: Представяна е програма за изпитване на автоматизирана система за комплексен неразрушаващ контрол на структурните и физикомеханичните свойства на образци и изделия от метални материали. Системата се състои от няколко модули уреда, които измерват по два неразрушаващи информационни параметри, основани на методи с различни физически основи (магнитни, акустични, термоелектрически и др.). В работата са представени само два модули уреда - MULTITEST МС010 за изследване на феромагнитните материали, който използва методите за измерване на магнитното шумово напрежение и магнитоакустичната емисия и MULTITEST CD010 за изследване на метални материали с методите за измерване на скорост и коефициент на затихване на ултразвука във вълни в материалиите. Разработени са - обща методика на системата за изпитване/измерване, както и методики за калибриране и метрологично осигуряване на уредите в режим на работата на системата при комплексен неразрушаващ контрол. Направени са изводи за достоверността на измерванията на системата при използване при комплексен неразрушаващ контрол на метални материали.

Ключови думи: КОМПЛЕКСЕН НЕРАЗРУШАВАЩ КОНТРОЛ

1. Въведение

Методите на магнитния шум и магнитоакустичната емисия, основани на ефекта на Баркхаузен, все по широко се използват за неразрушаващи изследвания на структурата и физикомеханичните свойства на феромагнитни материали. Техните информационни неразрушаващи параметри се регистрират при въздействие на променливо магнитно поле с ниска честота върху изследвания феромагнитен материал, при което се получава обективна, повторяща се информация [1,2,3,5,6]. На основата на тези методи е разработен модулния уред MULTITEST МС010, който измерва числовите характеристики на магнитния шум и на магнитоакустичната емисия – магнитно шумово напрежение и средноизходнастно напрежение на магнитоакустичната емисия. Съществува ултразвуков метод при който се измерва скоростта и затихването на ултразвука в материалиите. Той е подходящ за изследване структурата и звуковата на материалиите, чрез предоставяне на информация от обемните ултразвукови вълни, преминаващи през цялото сечение на материал [4]. На основата на този метод е разработен уред MULTITEST CD010, който измерва скоростта на разпространение на надлъжна ултразвукова вълна и коефициента на затихване на ултразвука в изследвания материал. Тези модулни уреди могат да работят самостоятелно или обединени в автоматизирана система за комплексен безразрушителен контрол на метални материали.

2. Цел на работата

Основна цел на настоящата работа е да се създаде обща методика за изпитване/измерване, структурата и съдържанието на която трябва да се спазва при разработването на конкретни методи за комплексен безразрушителен контрол. Да се разработят и анализират видовете и условията на които трябва да отговарят еталоните и сравнителните образци със съответните групи на сравнителни образци. Като критерий за класифициране се извършват изпитвания и анализ на системата със сравнители образи, получени с помощта на методика за комплексен безразрушителен контрол на метални материали.

3. Основни принципи на комплексния неразрушаващ контрол

Основен принцип на комплексния неразрушаващ контрол е, че практическата целесъобразност от увеличаването на неразрушаващите информационни параметри, се определя от вероятността от правилна оценка на свойствата на контролируемите образи или материали, класифицирани чрез един информационен параметър и сравнена с вероятността от правилната оценка на материалите, класифицирани чрез едновременно измерване на два информационни неразрушаващи параметри. Логично е, че при получаването на недостатъчна информация за контролируемия материал или изделие при прилагане само на един метод, използването на подходящо подбран втори метод ще увеличи вероятността за правилна оценка на материалите. За да се оцени тази вероятност, данните от неразрушаващия контрол се подлагат на статистическа обработка. Тя обхваща следните етапи:

3.1. Интервalli оценки

Определят се средните значения и интервали оценки на серните измервания, изпълнени по един или два неразрушаващи информационни параметри. За един или два параметъра се пресмятат:

а). Еднопараметрова интервална оценка(фиг.3б).

б). Двупараметрова интервална оценка (фиг.4).

3.2. Критерий за класифициране

Използва се система с предварително обучаване чрез сравнителни образи. Образите формират характеристични области чрез доверителни интервали с определена степен на вероятност. Такава система представлява членовете на едновременно по 2-5 независими измервания на всеки информационен безразрушителен параметър върху контролируемите уреди, пресмята се средната стойност на измерването, ако тя се в границите на доверителния интервал, то материала (детайла) принадлежи към съответната група.

3.3. Програмно осигуряване

Разработен е софтуер за събиране, анализ и оценка на експериментални данни, получени от измерването на неразрушаващите информационни параметри върху образи и изделия от метални материали. Използван са програмите MatLab за оценка и LabVIEW за онлайн визуализиране на резултатите.

5. Апаратура и методики за изпитване

5.1. Апаратура за изпитване

Фиг. 1. Външен вид на системата с изпитвателни клещи DK100 и уреди MULTITEST MC010 и MULTITEST CD010

На фиг. 1 е показан външен вида на двата модулни уреда и приспособлението (измервателни клещи) за провеждане на комплексния неразрушаващ контрол. Всеки уред може да измерва самостоятелно по два неразрушаващи информационни параметъра. Новост при тази автоматизирана система е, че може да се измерват едновременно два неразрушаващи параметри с различаваща се физична основа (например съчетание на магнитен с акустичен параметър или електрически с ултразвуков и др), което повишава достоверността на контрола. Възможно е измерването на и други параметри с различаваща се физична основа – например термоелектрически, вихротокови и др.

5.2. Програма за измерване/изпитване

Тя е разработена съгласно европейските норми за оценка на сигурността на измерването и съдържа следните раздели:

- обект на измерване/изпитване;
- цел на измерване/изпитване;
- условия и режими, при които се провежда изпитването;
- описване на метода за всяка проверка на параметъра със списъка на проверяваните параметри от раздел "Обем на измерване/изпитване" на методиката за измерване/изпитване;
- обработка, анализ и оценка на резултатите от измерването за всеки метод за отделен проверяван параметър;
- отчетност.

5.2. Методика за калибровка на модулните уреди

- Обект на калибровка. Обект за калибровка са модулните уреди MULTITEST MC010 и MULTITEST CD010. Те са конструирани като завършени автономни уреди, с цел да може да се използват за самостоятелно контролиране и работата и режимите на измерване са описани подробно в Ръководството за използване.

- Вид на калибровката. За калиброва на модулните уреди "MULTITEST MC010" се извършва със сравнителни образци за възпроизвеждане на резултатите. Те са два вида - цилиндрични с шиловани плоскопаралелни напречни повърхини за допирен преобразувател и цилиндрични с шилована цилиндрична повърхини за проходен преобразувател. Калибровката на уреда MULTITEST CD010 се извършва от стъпаловиден еталонен образец, показан на фиг. 2.

Фиг. 2. Съставен еталонен образец за калибровка

- Основни характеристики за калибровка. Необходимо е да се извърши проверка на възпроизвежданата на работа на системата преобразувател-модул уред чрез използване на сравнителни образци и арико желязо. При уреда "MULTITEST MC010", с цел постигане на възпроизвеждане е възможно коригиране на режимите на намагнитване. Възпроизвежданата се проверява чрез статистическа обработка на предходните и получените данни и оценка на близостта им определен критерий. При уреда MULTITEST CD010, основни характеристики за калибровка са: - линейност на ултразвуковия дебеломер и линейност на оптическия дебеломер. Извършва се стъпаловидна еталонна дъска РКБ 1 (фиг.2). Измерват се две или повече калибровчни дебелини (А,В,С,D) на еталона и по тях се настройват дебеломерите.

- Процедура за калибровка. За уреда MULTITEST CD010 основните действия при калибровка са следните: - Избор на представителен сравнителен образец за лабораторния изследовател с използване на следната информация: - вид изследван материал (марката, технология на производство, твърдост, механични и еластични свойства и др.). С него се последователно се построяват следните зависимости (фиг.3):

- Построяване на зависимости от вида $E_{NB} = F_{MAE}(f)$;
- Построяване на зависимости от типа $E_{MAG} = F_{NC}(f)$;
- Избира се режим на намагнитване при който $I_{opt} = I_{N}/f = max$, където основните характеристики за калибровка са: $I_{N}$ - големина на тока на намагнитването, $f$ - честотата на намагнитвания ток; $E_{NB}$ - магнитно шумово напрежение; $E_{MAG}$ - напрежение на магнитоакустичната емисия.

При оптимален ток $I_{opt}$ се провеждат изпитания със сравнителни образци от контролирана материал. Снемат се характеристиките на $E_{NB}$ и $E_{MAG}$ и се сравняват с получените стойности за сравнителните представители лабораторни образци. Въвеждат се получените стойности. Доказа се приложимостта на режима на намагнитване за комплексен неразрушаващ контрол на изпитвания материал. Калибрирането и настройката се извършват един път за дадена серия образци. Калибровката се извършва по следния алгоритъм:

- Чрез автоматично сканиране се получават зависимости $E_{NB}(f)$ за еталонните образци и за няколко групи стандарти образци от контролируемия материал. Получените зависимости се апроксимират с функция от вида:

$$E_{NB} = (a_0 f^2 + b_0 f + c_0)^{1/2}$$ (1)

От зависимостите (1) се определя оптималната честота $f_{opt}$, и ней се определят зависимостите на шумовото напрежение $E_{NB}$ от тока на намагнитване $I_{opt} = E_{NB}(I_{opt})$. Получените зависимости се апроксимират с функция от вида:

$$E_{NB} = a_1 \exp(b_1 \{\exp(c_1 I_{opt})\})$$ (2)

Оптимизирането на технологичния режим на контрола по отношение на честотата $f$ и тока на намагнитване $I_{opt}$ се постига чрез анализ на получаваните зависимости с използване на процедурата за намиране на максималните отличия между стойностите на апроксимиранияте данни.
а). Определя се оптимална честота и оптимален намагнитващ ток. Зависимостите (1) се апроксимират с квадратни уравнения от вида:

\[ f_0^2 + af + c = 0, \] (3)

корените на които представят оптималната честота \( f_0 \) (opt) и след това на тази честота се получават зависимостите \( E_{NB} = \frac{\gamma MAE}{E_{MAE}} \) за групите стандартни образци (фиг.2). Тези зависимости се апроксимират с нелинейни уравнения от вида:

\[ \exp(\phi(I_{NOpt})) - A \exp(\phi(I^{2})) = 0, \] (4)

б). На уравнения (4) се намират максималните отличия между стойностите на апроксимирани данни и от тях се намира оптималната стойност на намагнитващия ток \( I_{NOpt} \) - (фиг.3). На този ток на намагнитване ще се измерват \( E_{NB} \) и \( E_{MAE} \) в реални образци с непознати структурно-механични характеристики.

Основните действия за калибриране на уреда MULTITEST CD010 са следните: Настройката на работния диапазон се определя съгласно инструкцията на уреда, според минималната и максималната дебелина на контролируемия материал така, че диапазонът на реалните дебелини на материала да се възпроизвести в работния диапазон. За целта се правят две последователни измервания върху два участъка от еталона, като се измерва относителната дебелина на калибровъчните дебелини, измервани с оптоелектронен датчик.

За пресмятане на скоростта на ултразвука се използва формулата:

\[ c = \frac{k(d_{e1} - d_{e2})}{d_{e2} - d_{e1}} \] (6)

където: \( d_{e1} \) - относителна дебелина на измерените два участъка в еталона (фиг.2); \( d_{e2} \) - българска дебелина на същите два участъка, измерена с оптоелектронен датчик; \( d_{e1} \) - относителна дебелина на същите два участъка, измерена с ултразвука.

За пресмятане на скоростта на ултразвука се използва формулата:

\[ \delta t = \frac{A_{e}}{2d_{e} \Delta n} \] (7)

където: \( \delta t \) - скорост на ултразвука в еталона (m/s); \( k \) - коефициент на пропорционалност, отчитащ външните условия; \( d_{e} \) - относителна дебелина на материал, измерена с ултразвука; \( A_{e} \) - активна дебелина, измерена с оптоелектронен датчик; \( \Delta n \) - число възволнители на сравнениите импулси; \( A_{e} \) - амплитуда на сравнениите ултразвукови импулси.

- Приспособления. За прилагането на ултразвуковия метод, при калиброване се използват специално разработените изпитвания клещи DK100 с цел едновременното измерване на оптималните дебелини на образците и ултравуковият пистеобразувател.

5.3. Метрологично осигуряване

Метрологичното осигуряване на уреда MULTITEST MC010 се реализира чрез използване на следните типове сравнителни образци:

- Сравнителен образец за външния диапазон на максималната дебелина на контролируемия материал. За целта се правят две последователни измервания на относителната дебелина на измерените два участъка от еталона, измерена с оптоелектронен датчик; същите два участъка, измерени с ултразвука. Сравнителни образци се подготвят от материали, като са изрязани от структурата и механичните характеристики на образцовите образци след термообработка.

- Съпоставен изложен блок РКБ 1(фиг.2). Измерват се две или повече калибровъчни дебелини (A,B,C,D) на еталона и оптимална дебелина за възпроизвеждане на резултатите при работа с системата.

Метрологичното осигуряване на уреда MULTITEST CD010 се реализира чрез използване на следните типове сравнителни образци:

- Сравнителен образец за въвърхната дебелина на измерванията. Изработва се от нисковъглеродно (армко) железо с изчистена до \( R_s < 0.3 \) mm повърхност, с атестирана скорост на ултразвукова вълна.

5.4. Обща методика за изпитване

С така калибрования уред може да се пристъпи към изпитване на системата:

- Обект на изпитване/измерване. Обект за изпитване е автоматизираната система MULTITEST за комплексен безразрушителен контрол на структурата и механическите свойства на метални материали. В състава на автоматизираната система MULTITEST влизат: Модулен уред MULTITEST MC010 за измерване на магнитоциклоновите и магнитоакустични характеристики на образци и изделия от феромагнитни материали; Модулен уред MULTITEST CD010 за измерване на скорост и затихване на ултразвукови вълни в метални материали; Приспособления – изпитвания клещи DK100, съответно преобразуватели и лаптоп за настройка и обработка на резултатите, Необходима документация и софтуер към системата (Инструкции за работа, сравнителни образци, База-данини, Методики за изпитване и измерване и др.).

- Цел на изпитването/измерването. Да се направи оценка на точността на метода и системата за измерване на сравнителните образци. Да се определят корелационните зависимости между безразрушителните информационни параметри и технологичните свойства на групите сравнителни образци. Да се установи контролнопригодността на съответния метален материал на образците към определените от техническото задание безразрушаващи измервания. Общи положения. Изпитванията/измерванията се провеждат на основата на следните нормативно-технически документи: Техническо задание; Ръководство за работа на апаратурата за изпитване/измерване;
- E1476 - 92 Standard Guide for Metal Identification, Grade Verification, and Sorting;
- E1316 - 92 Standard Terminology for Nondestructive Examinations;
- ISO 5725. Точност (истинност и прецизност) на методи за измерване и получените резултати;
- ISO Guide 35-1989;
- Инструкция за работа с модулен уред за измерване с методите на ултразвука MULTITEST CD010;
- Инструкция за работа с модулен уред за измерване с методите на Баркхаузен MULTITEST MC010;
- Инструкция за работа с автоматизираната система MULTITEST:
  - База-данини;
  - Софтуер за автоматизирана обработка и оценка на данните;
- EAL-EA-4/02 Expression of Uncertainty of measurement in Calibration;
- Протоколи от изпитванията/измерванията.

6. Експериментално изпитване и дискусия

За изпитване на системата за обработка и оценка на данни са разработени конкретни методики за неразрушаващ контрол на твърдостта (термообработката) на образци от легирания конструкционна стомана 43CrMo4. Подготвени са стандартни (сравнителни) образци, класифицирани в групи с еднакви механични свойства, съгласно т. 3.2. - система с предварително обучаване чрез сравнителни образци. Сравнителните образци са с размери Ф30x20mm, изработени са от прътов прокат и са подложени на различна степен на термообработка (закалка и отпуск). Принадлежността на стандартните образци към съответната група с еднакви механични свойства е потвърдена чрез химически анализ и механично изпитване на твърдост. На фиг. 3а и фиг. 3б графично е представена процедурата за определяне на контролопригодността и еднопараметровите интервални оценки на групите сравнителни образци за информационния неразрушаващ параметър \( E_{NB} \).

Аналогично се получават и еднопараметровите доверителни интервали на втория неразрушаващ информационен параметър \( E_{MAE} \) и след това, съгласно методиката, се изграждат двупараметровите интервални оценки - доверителни характеристични области на двата параметъра \( E_{NB} \) и \( E_{MAE} \), показани графично на фиг. 4.

На фиг. 3б се вижда, че при използването само на един информационния параметър \( E_{NB} \), доверителните интервали на групи 3 и 2 ще се застъпват, следователно са трудно различими. Подобен извод може да се направи и при използването само на информационния параметър \( E_{MAE} \). При комплексното използване на двата информационни параметъра, характеристиките области не се застъпват (фиг.4.), следователно се увеличава вероятността за правилно класифициране на контролируемия материал по структура или механични свойства. В зависимост от характеристиките области, формирани от сравнителните образци, например група 3 ако е избрана като годна, се пристъпва към класификация на реални дентални или материали. Аналогично системата може да извършва неразрушаващ контрол и с друг вид сравнителни образци от различни метални материали (ситеровани материали, чугун, катодни материали за батерии и др.), като се използват допълнителни неразрушаващи информационни параметри – например скорост и затихване на ултразвука, или термоелектрическо напрежение [5,6,7].

Фиг. 3. Еднопараметрова интервала оценка

Фиг. 4. Характеристични области от двупараметрова оценка за групите сравнителни образци.
7. Заключение

Доказана е възможността за комплексен неразрушаващ контрол на механичните свойства и структурата на образци от конструкционна стомана.

Класифицирането на образци и изделия от конструкционна стомана по групи с еднаква степен на термообработка (твърдост) е целесъобразно в много случаи да се осъществява с използване на двупараметров неразрушаващ контрол.

Изпитването на автоматизираната система доказва, че може да се използва при неразрушаващ контрол на термообработката и структурата на образци и изделия от метални материали.

Признателност: Тази работа е реализирана по проект М27/7 от 2018г., финансиран от Фонда за научни изследвания на МОН
